Abstract

This programme carries out two- and three-dimensional crystallographic Fourier summations. Input is from cards and output is numerically by cards or typewriter or as an alphameric plot by typewriter.

Machine requirements : Basic 20 K 1620 with card input/output. No additional features are required.

Programme details : The programme is written in SPS I and uses only fixed-point arithmetic. A Beevers-Lipson method is used for the summation. The first summation is carried out for a given value of x as the data are read in. The results are held in storage until all values for one kl have been treated. These are used directly in the second summation whose results are stored. The third summation is calculated and punched (printed) line by line. The data are read in again for the next value of x which is calculated automatically.

Range : Indices may not exceed 99. The summations are calculated at intervals of $n/100$ of the cell edge where n is any integer.

Storage requirements : The programme and working storage take up the whole machine. The first active statement in the symbolic programme defines the machine size so that the programme may be assembled to take advantage of any size machine. In a 20K machine 14388 storage positions are available to hold from 1797 to 1748 second summation results (e.g. a complete summation of 101 points with a maximum l index of 16) with from 3 to 101 third summation results.

Running time depends on the magnitude of the problem. An example is given in the text.

Remarks : A programme (ERA 235) is available to prepare the input of this programme from structure factor programme (ERA 164) output cards for any triclinic, monoclinic or orthorhombic space group except Fdd2 and Fddd.

1. Introduction

This programme has been written for the IBM 1620 data processing system with card input and output to carry out three- (and two-)dimensional Fourier summations for crystal structure analysis. It can be used to calculate electron or vector density at intervals of any desired multiple of one hundredth of the unit cell in each direction. The results are obtained as any or all of punched cards, numerical list or alphanumerical plot.

The programme was originally written (by DvdH while at the Institute for Cancer Research, Philadelphia, Pa., USA) for a 1620 with tape input and output (programme ICR1) and has been modified (by GSDK) to use card input and output and at the same time to increase the available working storage.

II. General Theory

The electron density can be evaluated at any point xyz (fractional coordinates are used throughout) of the unit cell by the expression :

$$\rho(xyz) = \frac{2}{V} \sum_{h=0}^{\infty} \sum_{k=0}^{\infty} \sum_{l=0}^{\infty} [A'(hkl)\cos 2\pi(hx+ky+lz) + B'(hkl)\sin 2\pi(hx+ky+lz)] \quad \text{II, 1}$$

It is impracticable to use this expression directly because of the amount of calculation involved. Thus in the case of a centrosymmetric space group with 2000 Fourier coefficients it would take the IBM 1620 about 140 hours to calculate a summation over 25x25x50 points.

The expression II, 1 can be rewritten following Lipson and Beevers (Proc. Phys. Soc., 1936, 48, 772) in the form :

$$\begin{aligned} \rho(xyz) = & \frac{1}{V} \sum_{l=0}^{\infty} \left[\sum_{k=0}^{\infty} \left\{ \sum_{h=0}^{\infty} (A(hkl)\cos 2\pi hx + E(hkl)\sin 2\pi hx) \cos 2\pi ky \right. \right. \\ & \left. \left. + \sum_{h=0}^{\infty} (F(hkl)\cos 2\pi hx + B(hkl)\sin 2\pi hx) \sin 2\pi ky \right\} \cos 2\pi lz \right. \\ & \left. + \sum_{k=0}^{\infty} \left\{ \sum_{h=0}^{\infty} (G(hkl)\cos 2\pi hx + C(hkl)\sin 2\pi hx) \cos 2\pi ky \right. \right. \\ & \left. \left. + \sum_{h=0}^{\infty} (D(hkl)\cos 2\pi hx + H(hkl)\sin 2\pi hx) \sin 2\pi ky \right\} \sin 2\pi lz \right] \quad \text{II, 2} \end{aligned}$$

$$\text{where } A = A'(hkl) + A'(\bar{h}\bar{k}\bar{l}) + A'(\bar{h}\bar{k}\bar{l}) + A'(\bar{h}\bar{k}\bar{l}) \quad \text{II, 3}$$

$$B = -A'(hkl) + A'(\bar{h}\bar{k}\bar{l}) + A'(\bar{h}\bar{k}\bar{l}) - A'(\bar{h}\bar{k}\bar{l}) \quad \text{II, 4}$$

$$C = -A'(hkl) + A'(\bar{h}\bar{k}\bar{l}) - A'(\bar{h}\bar{k}\bar{l}) + A'(\bar{h}\bar{k}\bar{l}) \quad \text{II, 5}$$

$$D = -A'(hkl) - A'(\bar{h}\bar{k}\bar{l}) + A'(\bar{h}\bar{k}\bar{l}) + A'(\bar{h}\bar{k}\bar{l}) \quad \text{II, 6}$$

$$E = B'(hkl) - B'(\bar{h}\bar{k}\bar{l}) + B'(h\bar{k}\bar{l}) - B'(\bar{h}\bar{k}l) \quad II, 7$$

$$F = B'(hkl) + B'(\bar{h}\bar{k}\bar{l}) - B'(h\bar{k}\bar{l}) - B'(\bar{h}\bar{k}l) \quad II, 8$$

$$G = B'(hkl) + B'(\bar{h}\bar{k}\bar{l}) + B'(h\bar{k}\bar{l}) + B'(\bar{h}\bar{k}l) \quad II, 9$$

$$H = -B'(hkl) + B'(\bar{h}\bar{k}\bar{l}) + B'(h\bar{k}\bar{l}) - B'(\bar{h}\bar{k}l) \quad II, 10$$

For centrosymmetric space groups $B(hkl) = 0$ and $A'(hkl)$ may be replaced by $F(hkl)$. The terms A, B...H should take account of multiplicity.

The use of the form (II, 2) reduces the number of arithmetic operations by a factor of about 15 at the expense of complicating the logical sequence of the programme. In fact it divides the calculation into three parts being the summations along the three reciprocal axes.

Define a set of terms A, B...H with the same indices hkl an amplitude and a set of amplitudes with the same indices kl a group.

In the first summation over h, sums (or pairs of sums) are calculated of all terms with different h indices in the same group kl and for all required values of x. Suppose we wish to calculate a Fourier synthesis with 1500 amplitudes in 250 groups and a maximum value of l = 15. Suppose further that we wish to calculate 26 sections each of 51x51 points. As each group gives rise to four sums (formula II,2) for each value of x, there will be $250 \times 4 \times 26 = 26000$ first summation results. Similarly, for each y value there will be two sums for each l and each x giving $51 \times 2 \times 16 = 1616$ sums for each section or 42016 sums for all 26 sections.

It is clearly impossible to store all the first or second summation results in a computer of the size of the 1620. There remain two possible courses of action. One is to punch the first summation results on cards which can then be sorted and reintroduced for the subsequent calculations. The other is to calculate one section at a time and to reintroduce the data for subsequent sections. The latter course is the one chosen here as it involves no manipulation of intermediate results, and consequently fewer possibilities of operator error.

The four first summations are :

$$M(klX) = \sum_{h=0}^{h \text{ max}} [A(hkl)\cos 2\pi hX + E(hkl)\sin 2\pi hX] \quad II, 11$$

$$N(klX) = \sum_{h=0}^{h \text{ max}} [F(hkl)\cos 2\pi hX + B(hkl)\sin 2\pi hX] \quad II, 12$$

$$O(klX) = \sum_{h=0}^{h \text{ max}} [G(hkl)\cos 2\pi hX + C(hkl)\sin 2\pi hX] \quad II, 13$$

$$P(klX) = \sum_{h=0}^{h \text{ max}} [D(hkl)\cos 2\pi hX + H(hkl)\sin 2\pi hX] \quad II, 14$$

in which X is the value of x for the particular section. These four values are accumulated in temporary storage locations and, as soon as a group k_1 has been completed, are used in the 2nd summation to give :

$$R(lXy) = \sum_{k=0}^{k \max} M(klX)\cos 2\pi ky + N(klX)\sin 2\pi ky \quad II, 15$$

$$\text{and } S(lXy) = \sum_{k=0}^{k \max} O(klX)\cos 2\pi ky + P(klX)\sin 2\pi ky \quad II, 16$$

for all required values of y . These pairs of four-digit sums are accumulated in blocks of constant l each containing N_y results where N_y is the number of points required in the y direction. This procedure requires that the data be sorted into blocks of increasing l , each of which contains groups of increasing k .

The third summation is

$$\rho(Xyz) = \sum_{l=0}^{l \max} [R(lXy)\cos 2\pi lz + S(lXy)\sin 2\pi lz] \quad II, 17$$

All N_z four-digit sums are calculated for each line of constant y and are then typed or punched line by line.

The storage required is thus $8N_y(l_{\max} + 1)$ locations for the second summation results and $4N_z$ locations for the third summation. In a 20K machine there are 14388 storage locations available so that it is possible to store at least 1748 second summation results. If fewer than 101 third summation results are required, this value will be greater.

The programme implies that sections are always calculated in the bc plane along rows parallel to c , which is not necessarily the most convenient presentation. It is possible to permute the indices hkl and the terms A-H to give any desired presentation. The permutations corresponding to the different presentations are given in Table II. A programme (ERA 235) is available to prepare input cards for this programme from structure factor output cards.

Table II.

Data formats for the different possible output orientations.

The data cards must always be sorted first on columns 9-10, then H-12

Running time. It is almost impossible to give a formula which would express the running time in terms of the many parameters involved. The first summation takes less than 240 msec per card so the card reading speed is the determining factor and the running time depends directly on the number of cards. The second summation running time is proportional to the number of groups kl . The third summation calculating time, to which must be added the output time, is proportional to $(l_{\max}+1) \cdot N_y \cdot N_z$. Thus, in order to reduce running time to a minimum it is best to make N_y small ; i. e. when only half a section is required it is faster to calculate for $y = 0(1) 0.50$ and $z = 0(1) 1.00$ than for $y = 0(1) 1.00$ and $z = 0(1) 0.50$.

As an example we give the timing of a particular run with 1735 hkl values (corresponding to 2632 hkl and $\bar{h}\bar{k}\bar{l}$ reflexions) in 127 different groups kl and with 14 different l values. For each section 51 rows each of 51 values were calculated.

First and second summations (giving 51×14 pairs of second summation results) : 9.75 min.

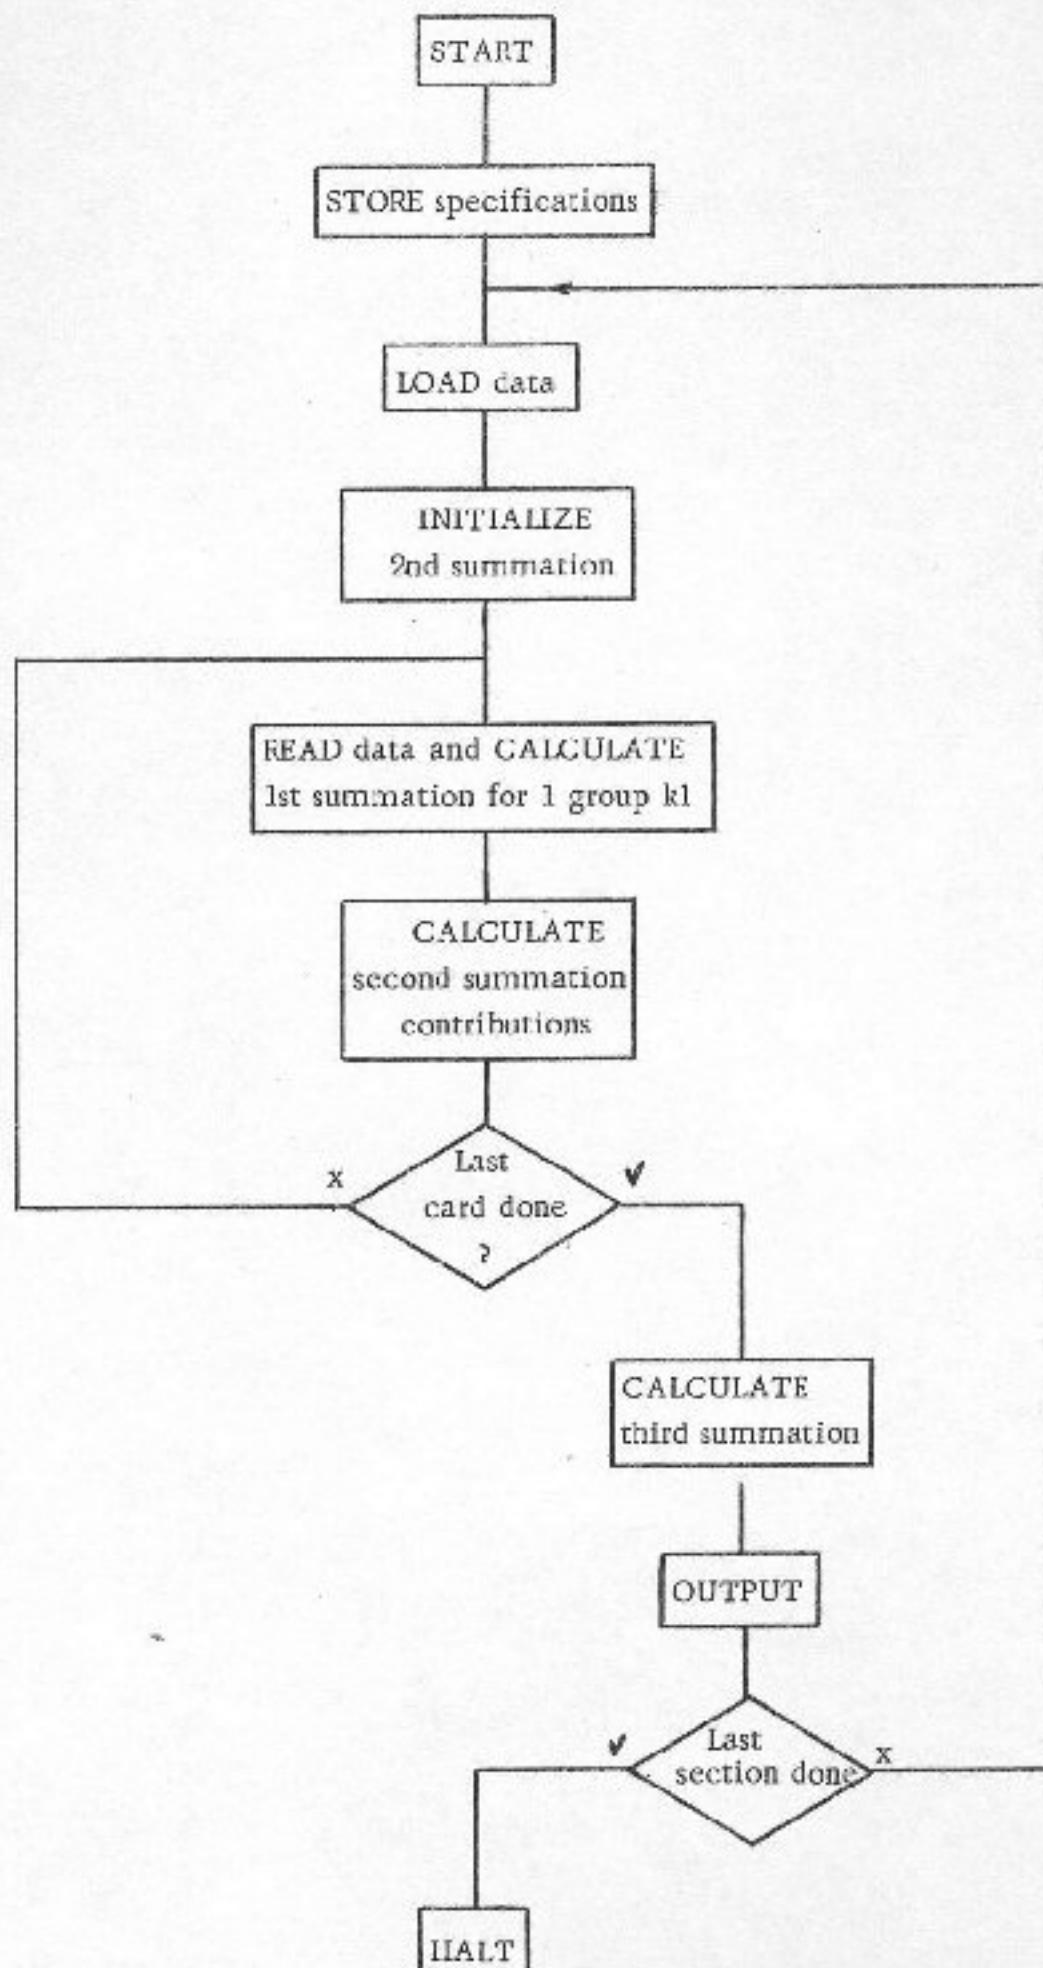

Third summation : 10.9 minutes.

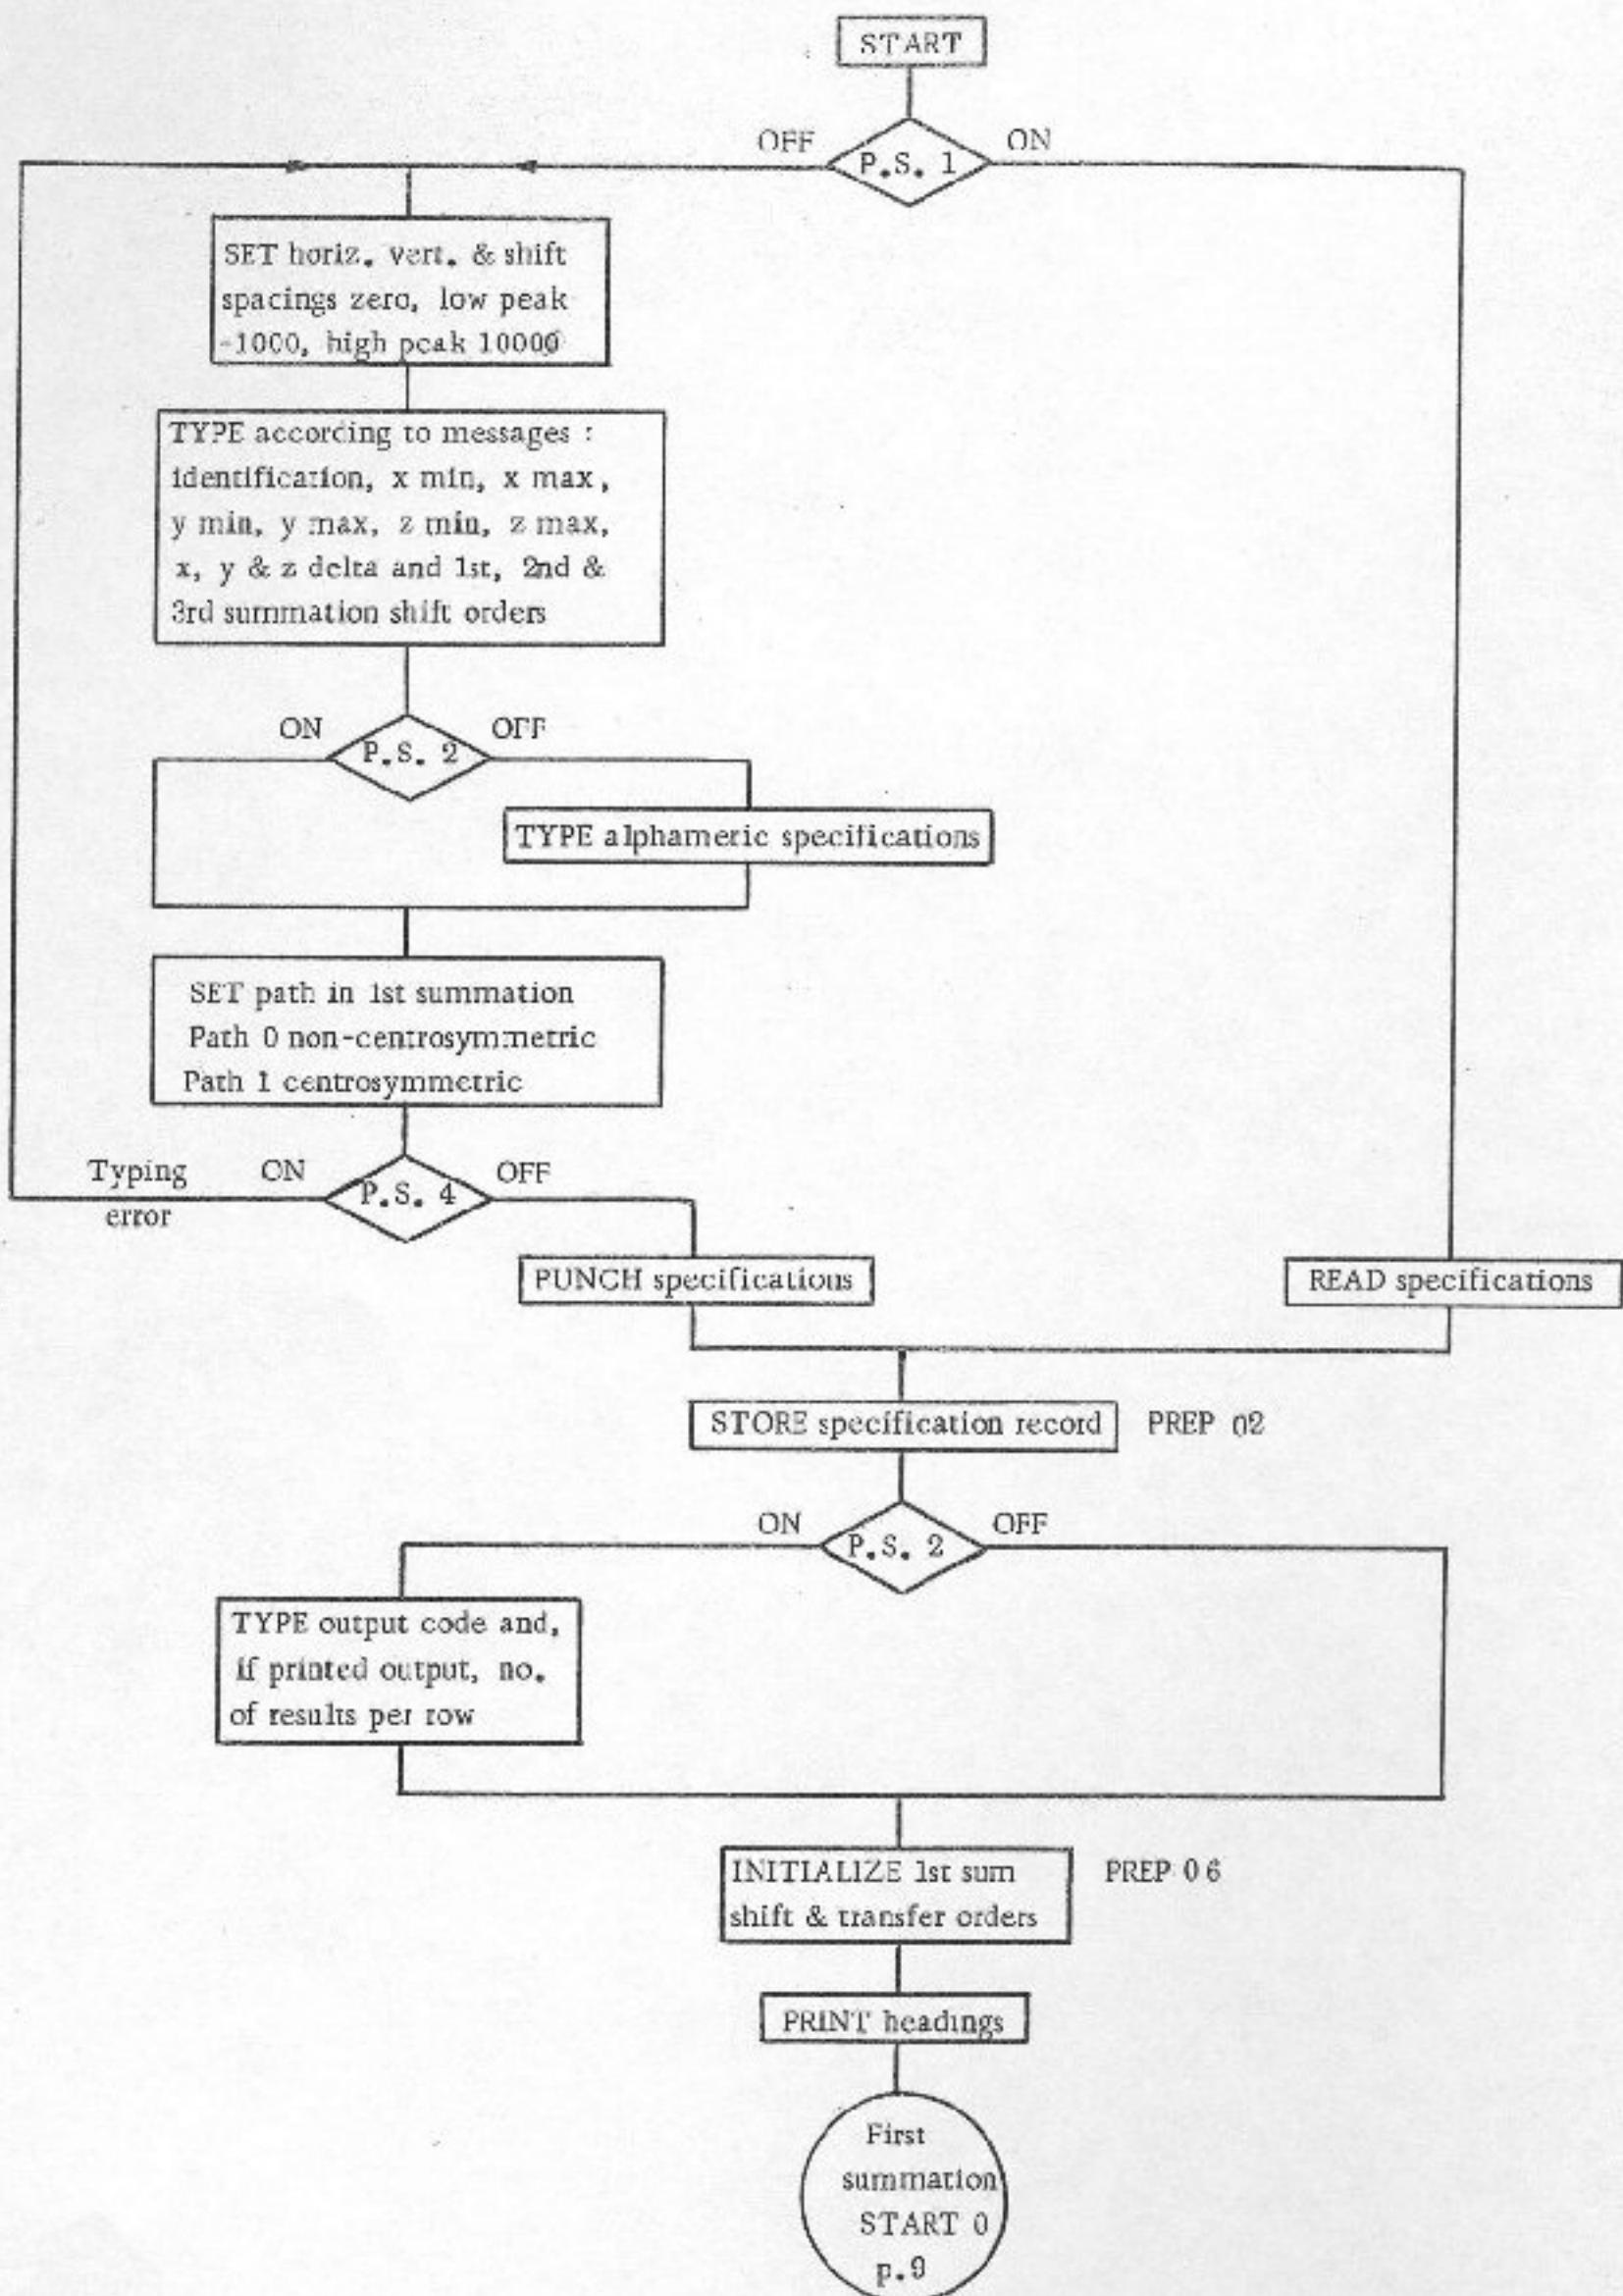

The READER NO FEED light was on continuously during the first summation (using a 250 c. p. m. card reader). It was extinguished at the end of each group kl while the second summation was being calculated.

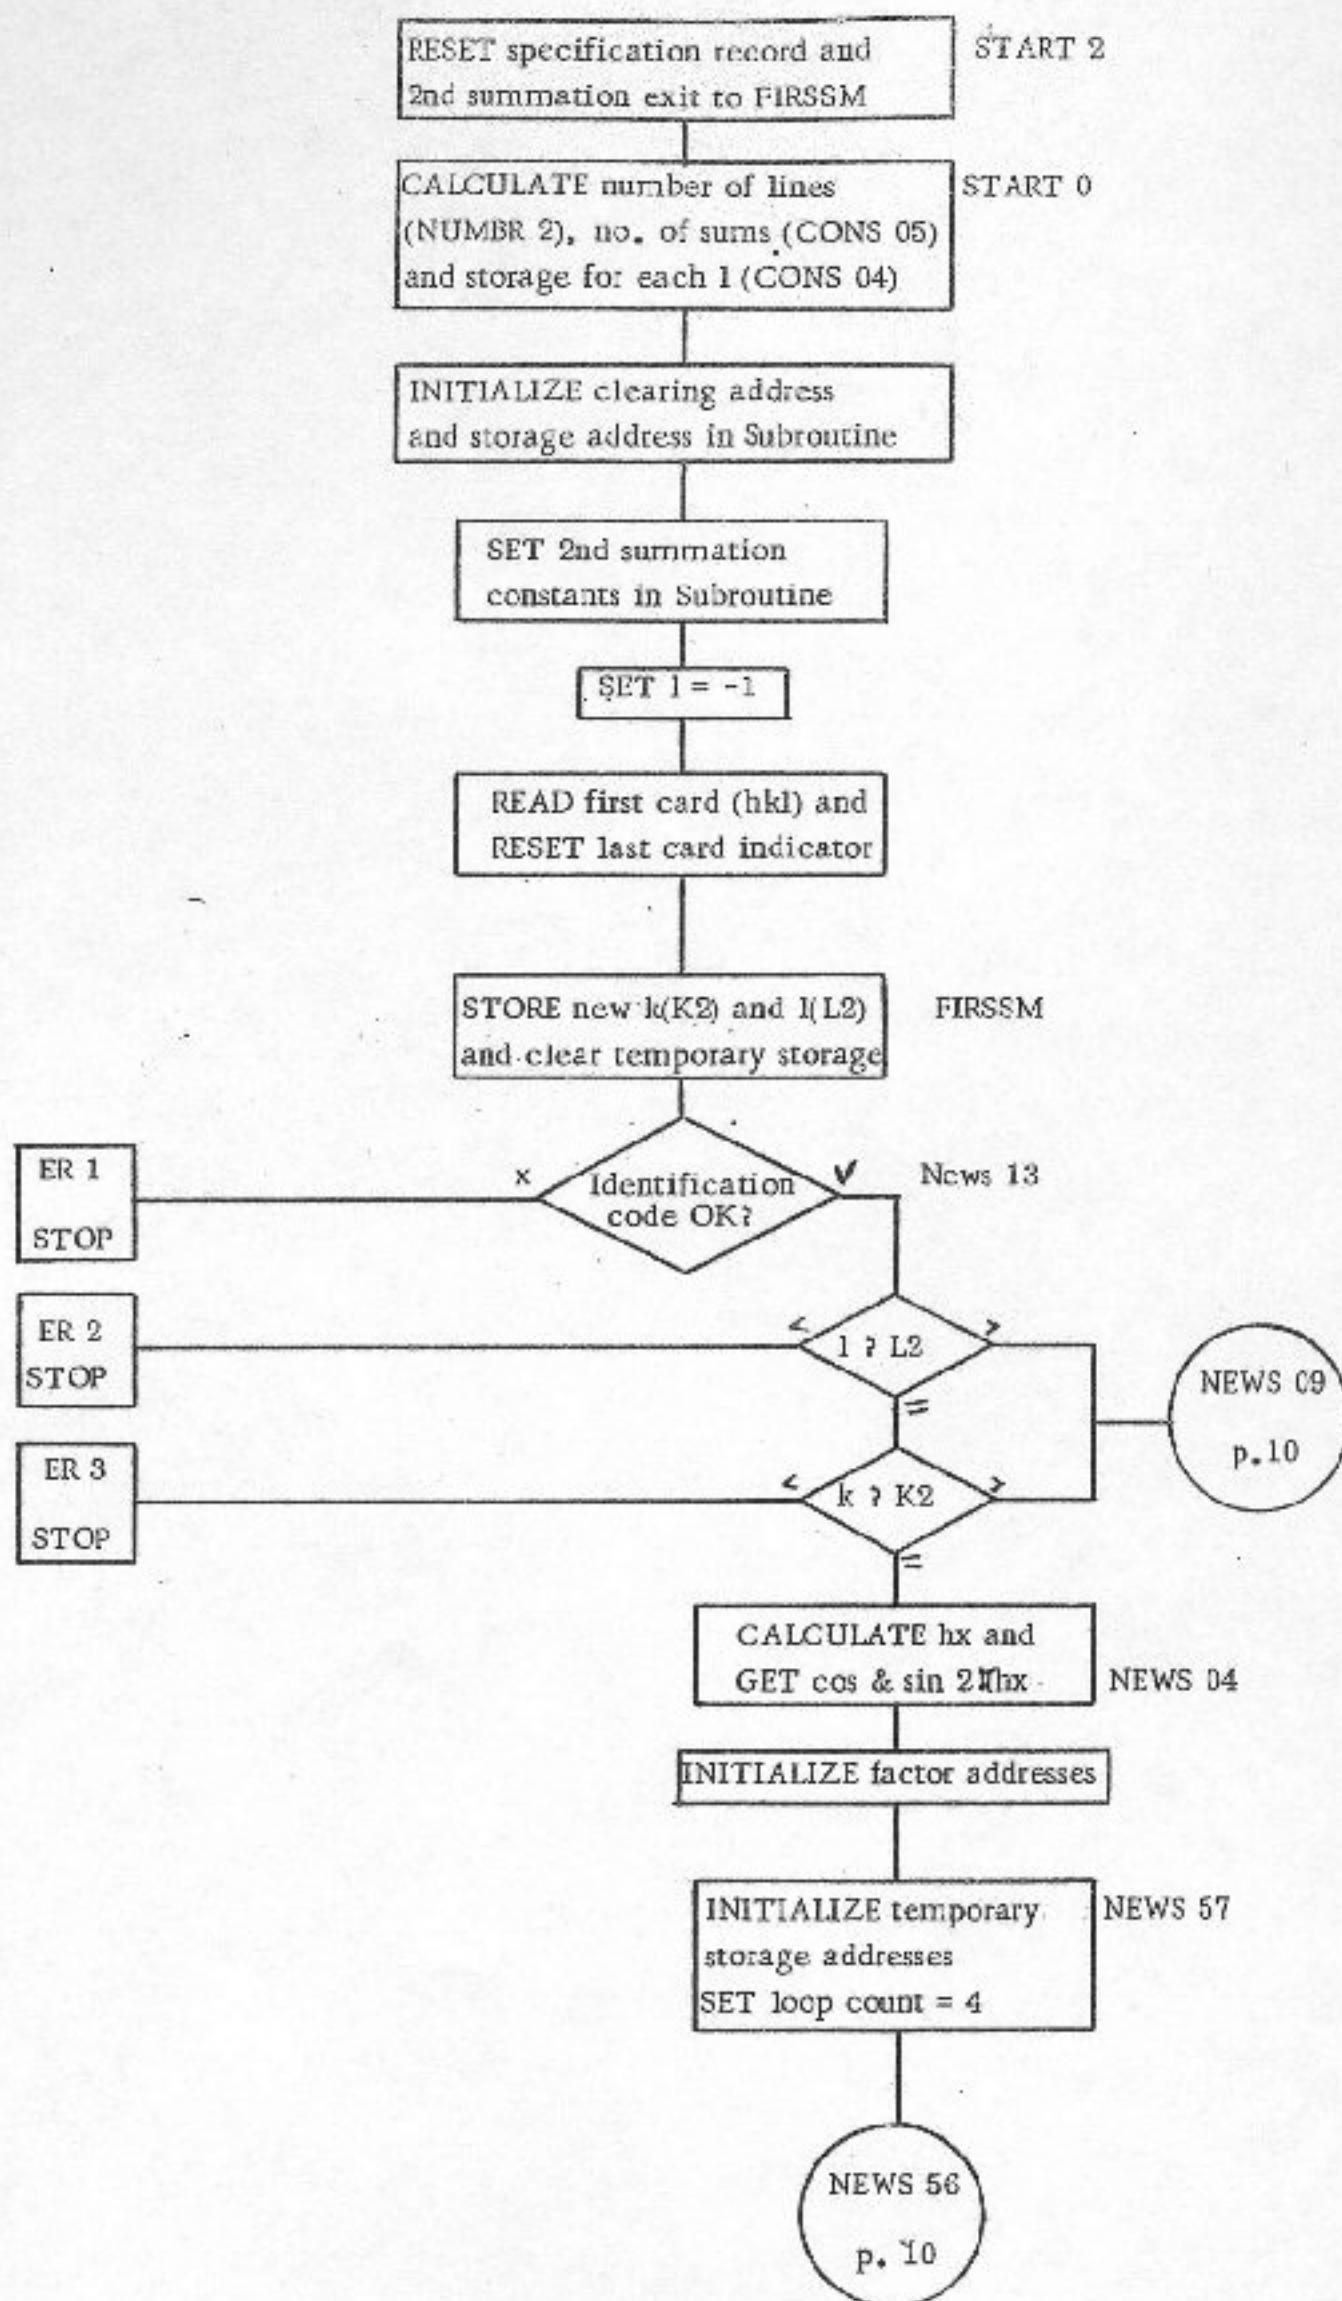

In the third summation results were punched only. Printing would greatly increase the time required.

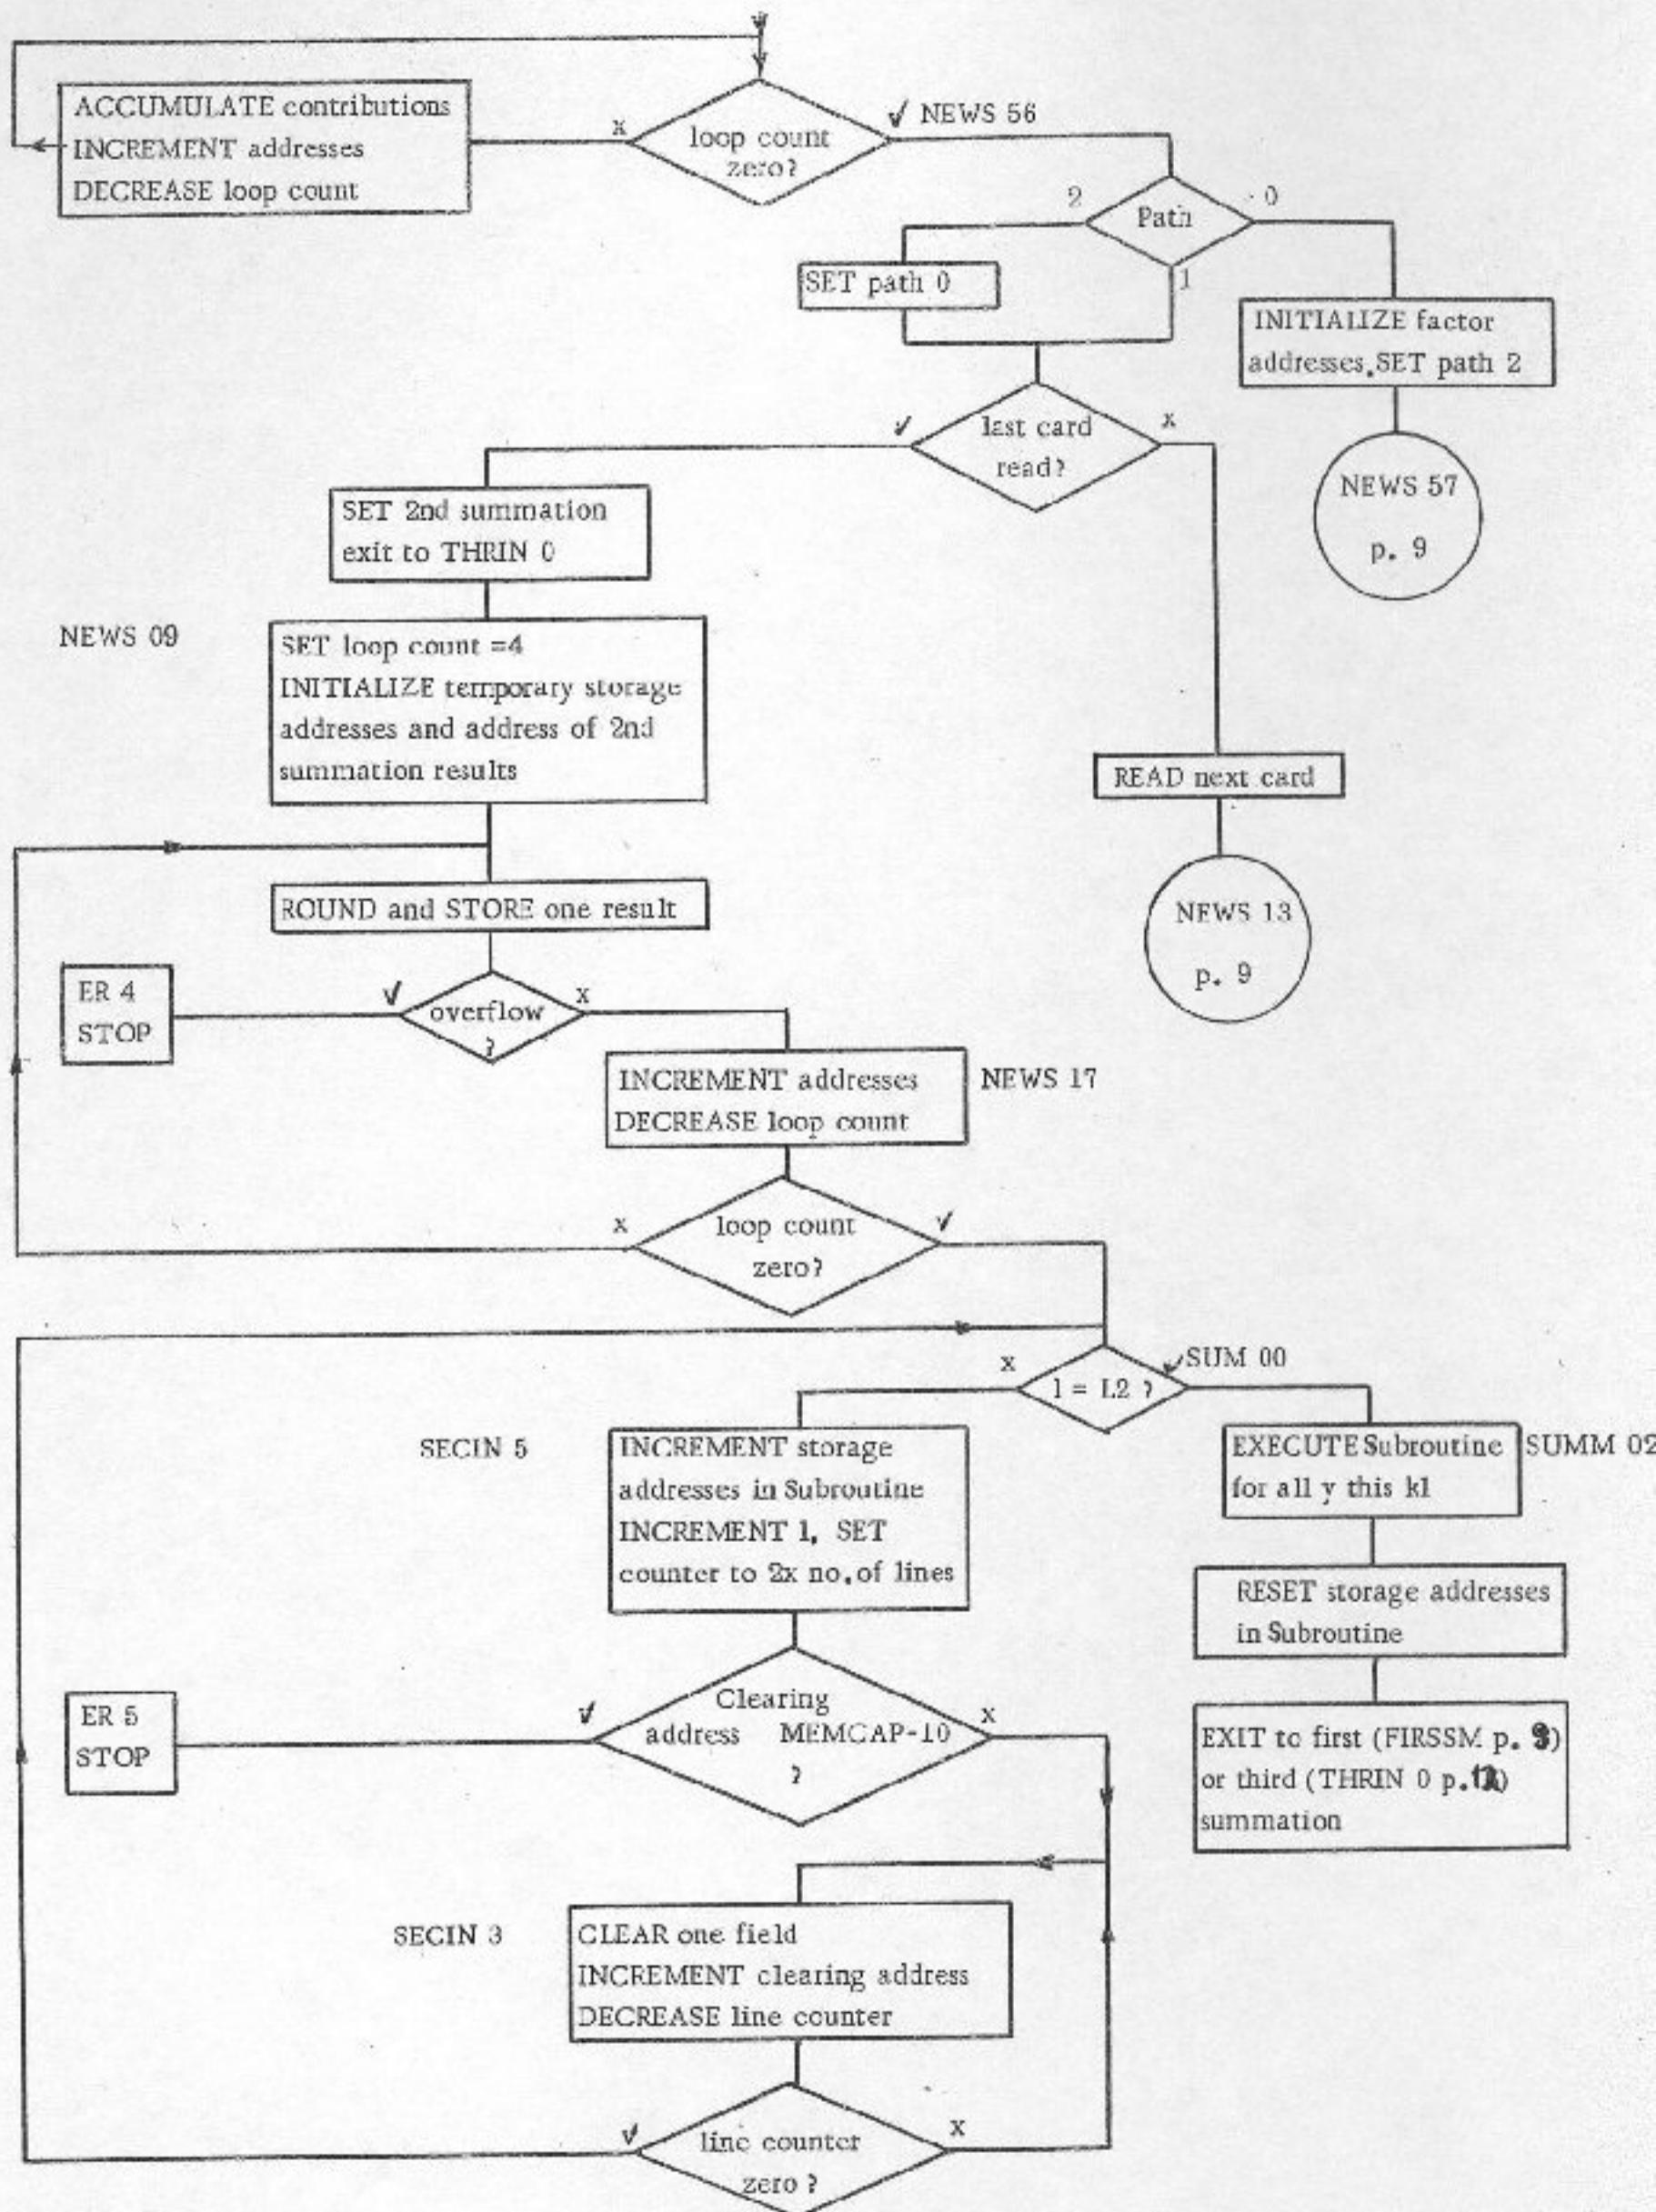

III. Flow charts.

General flow diagram.

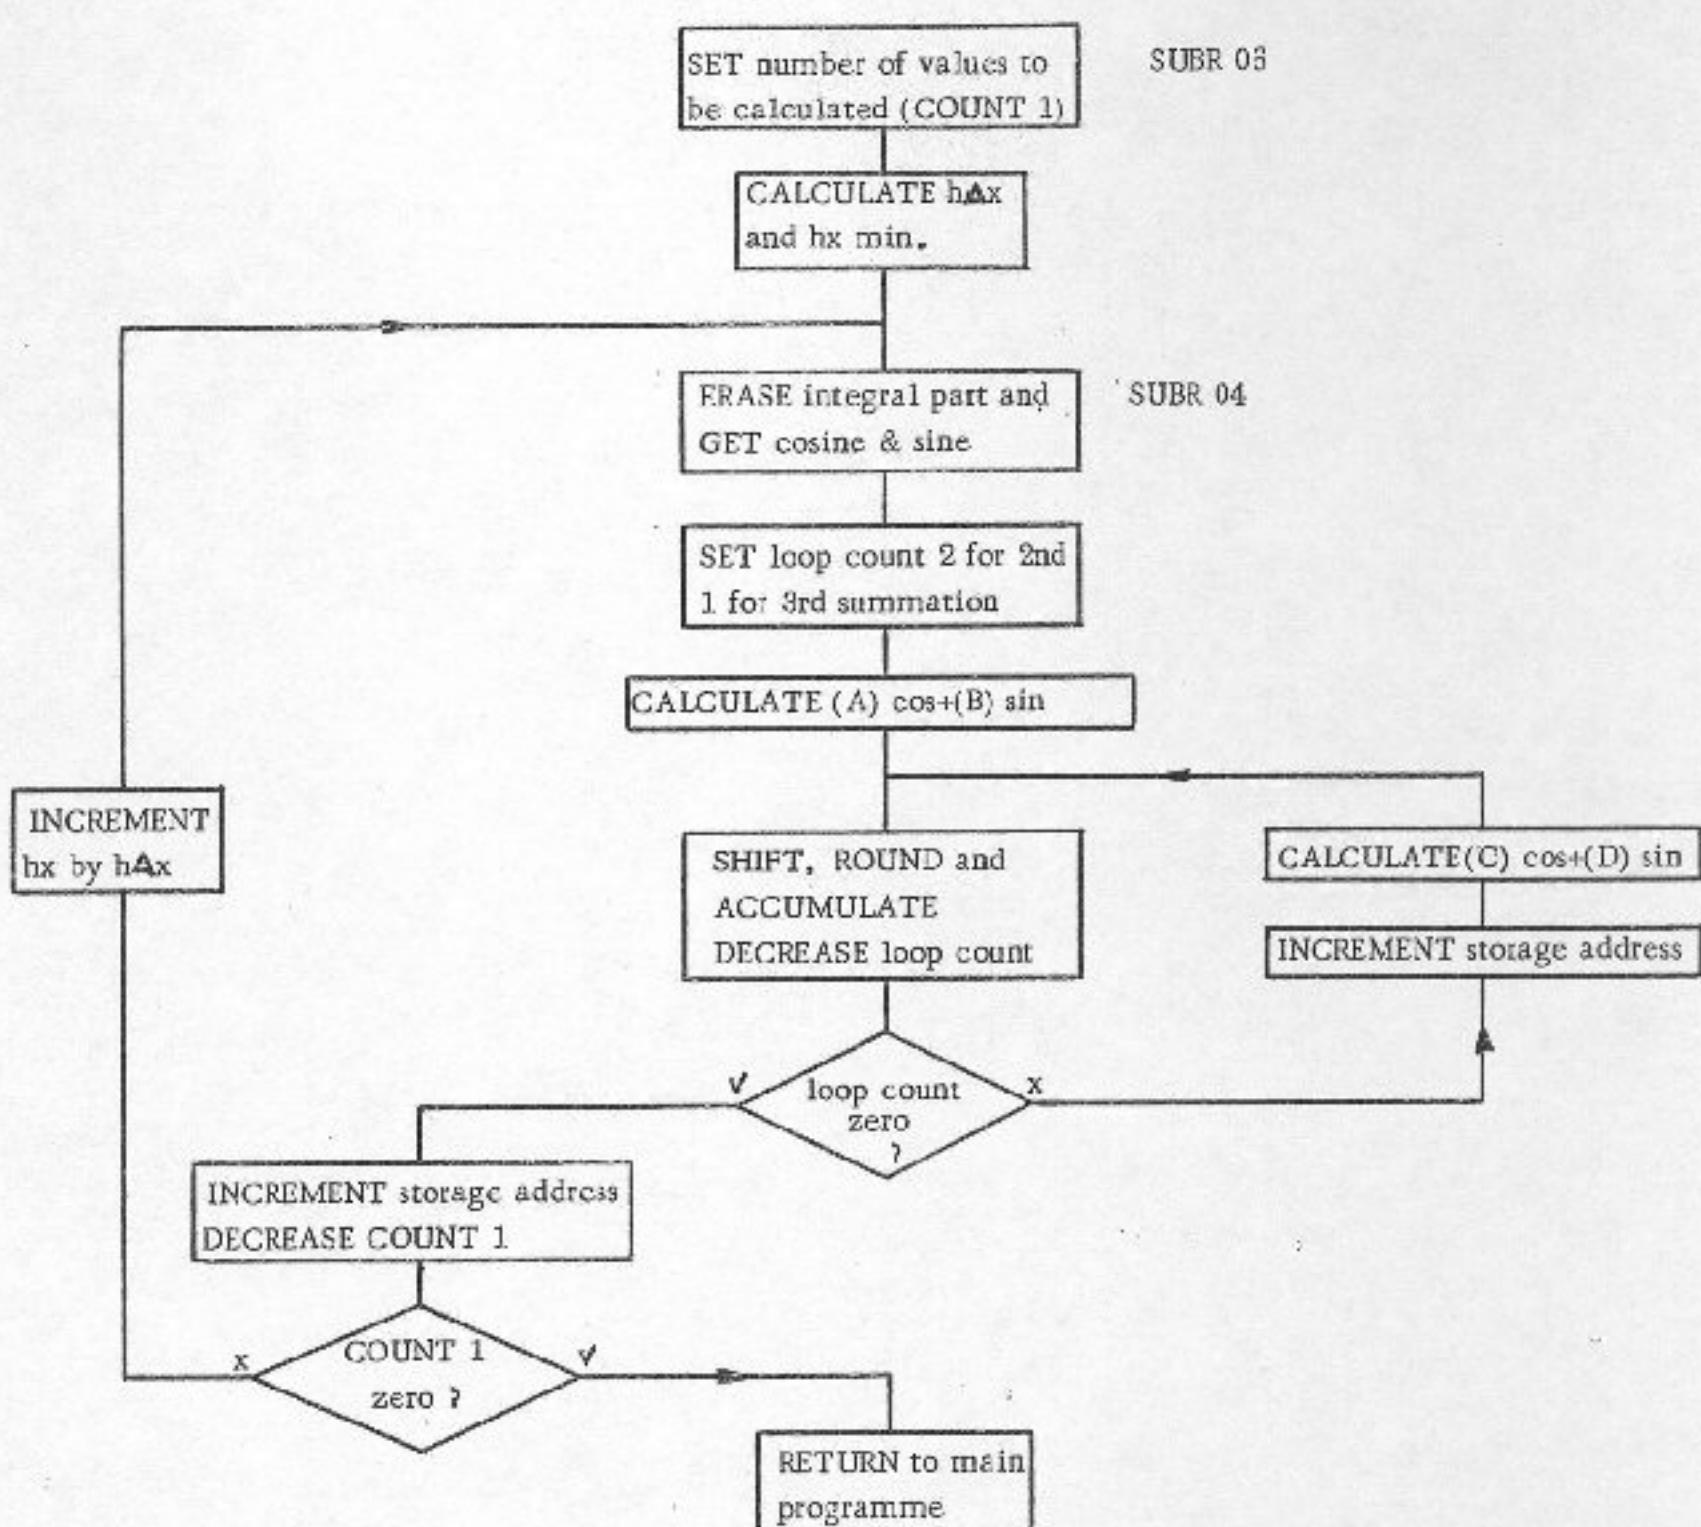

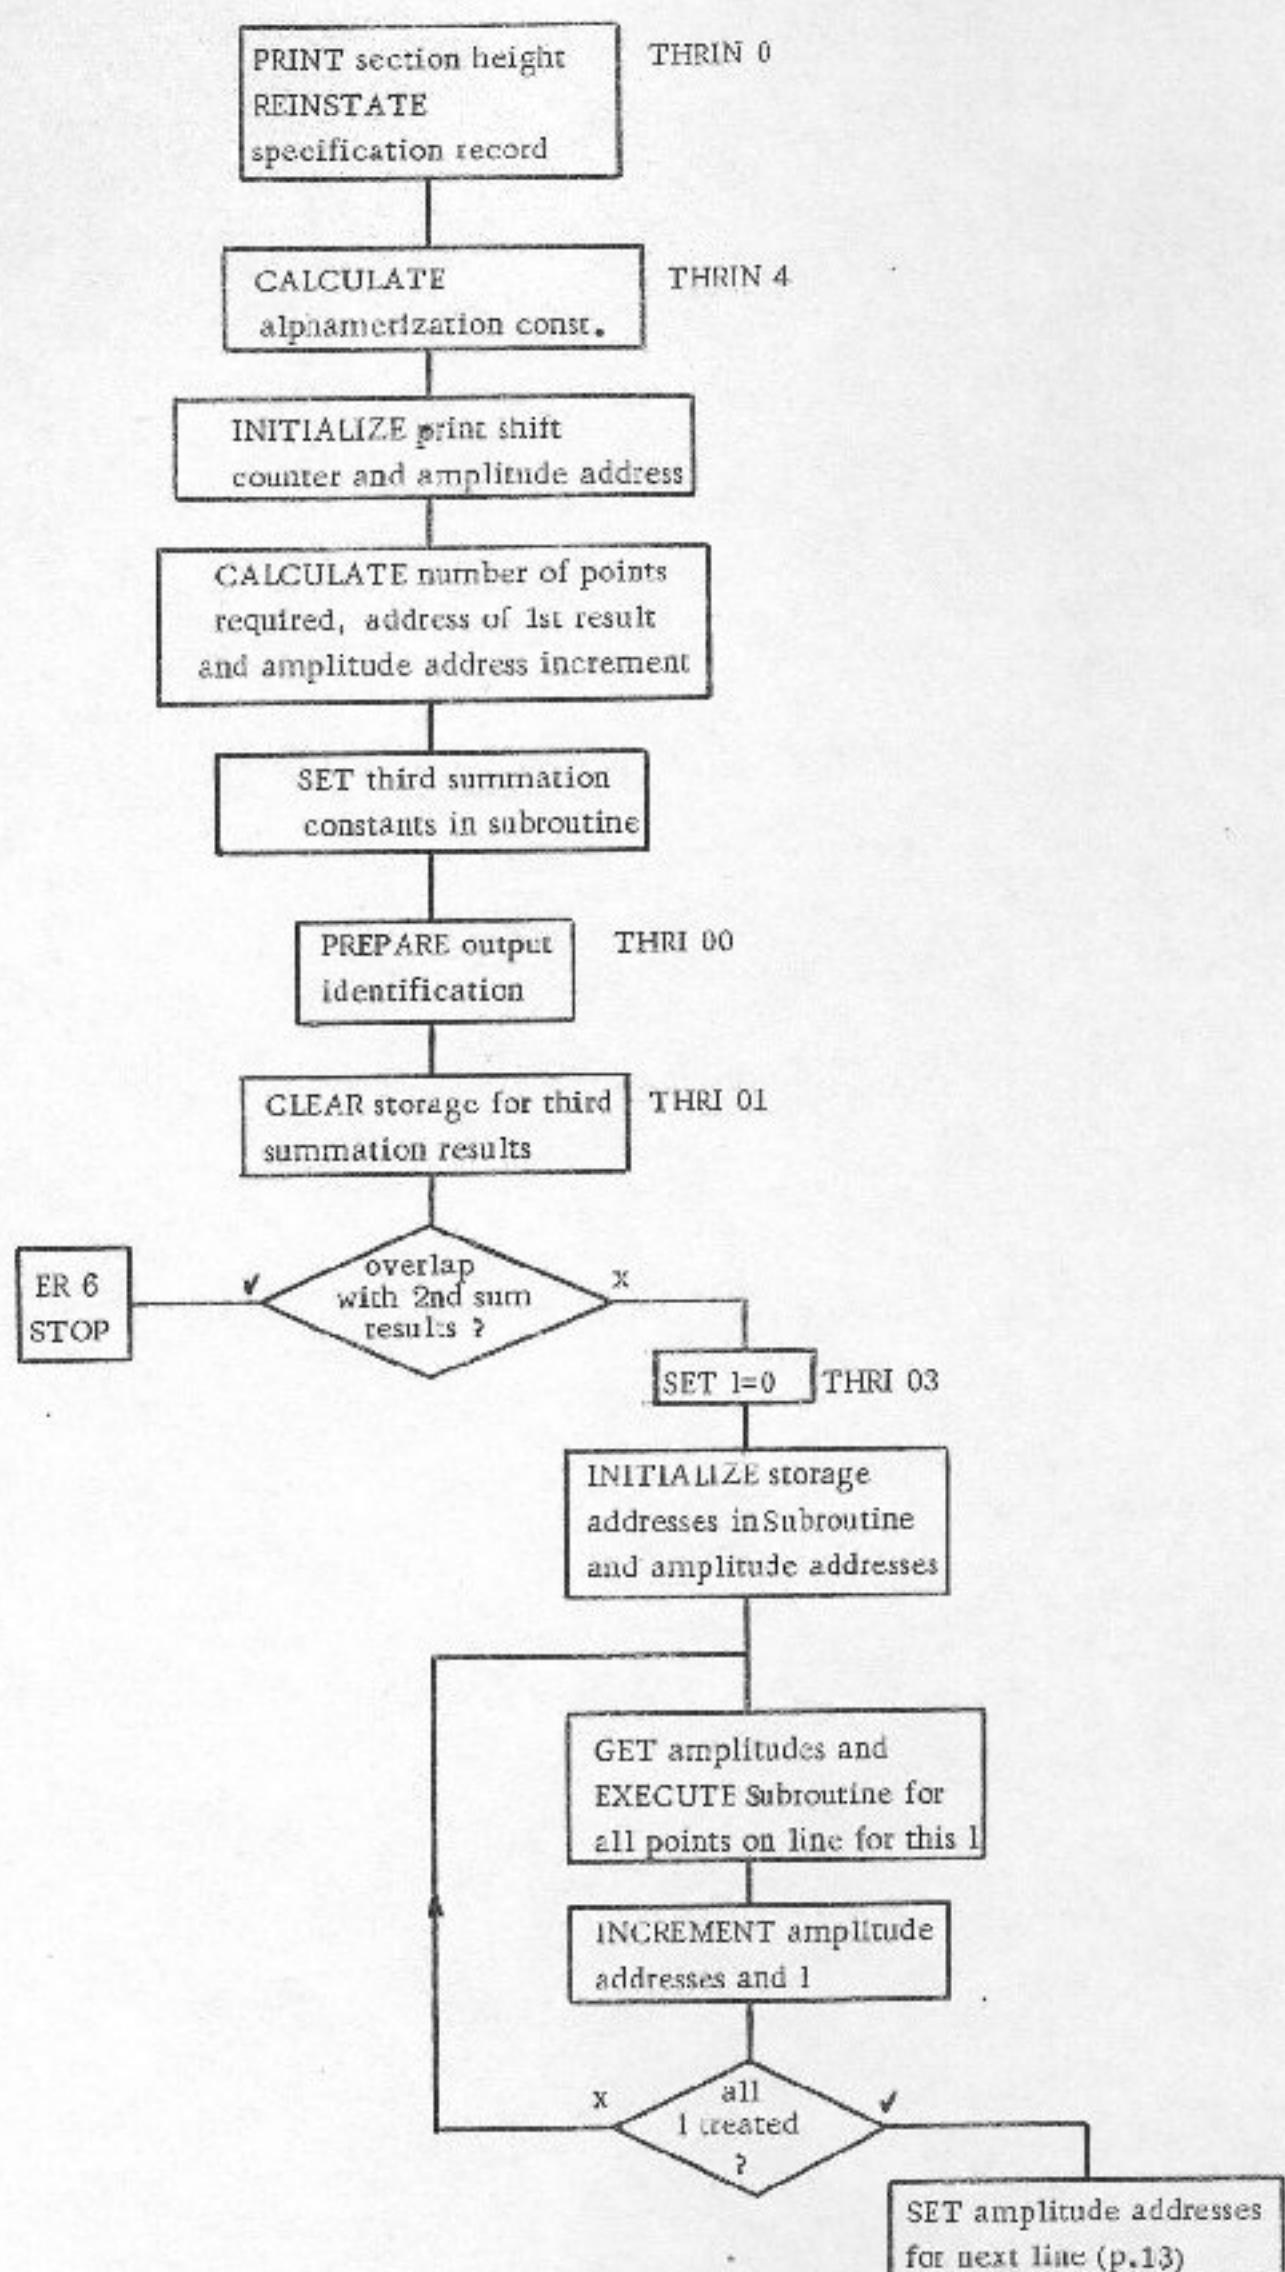

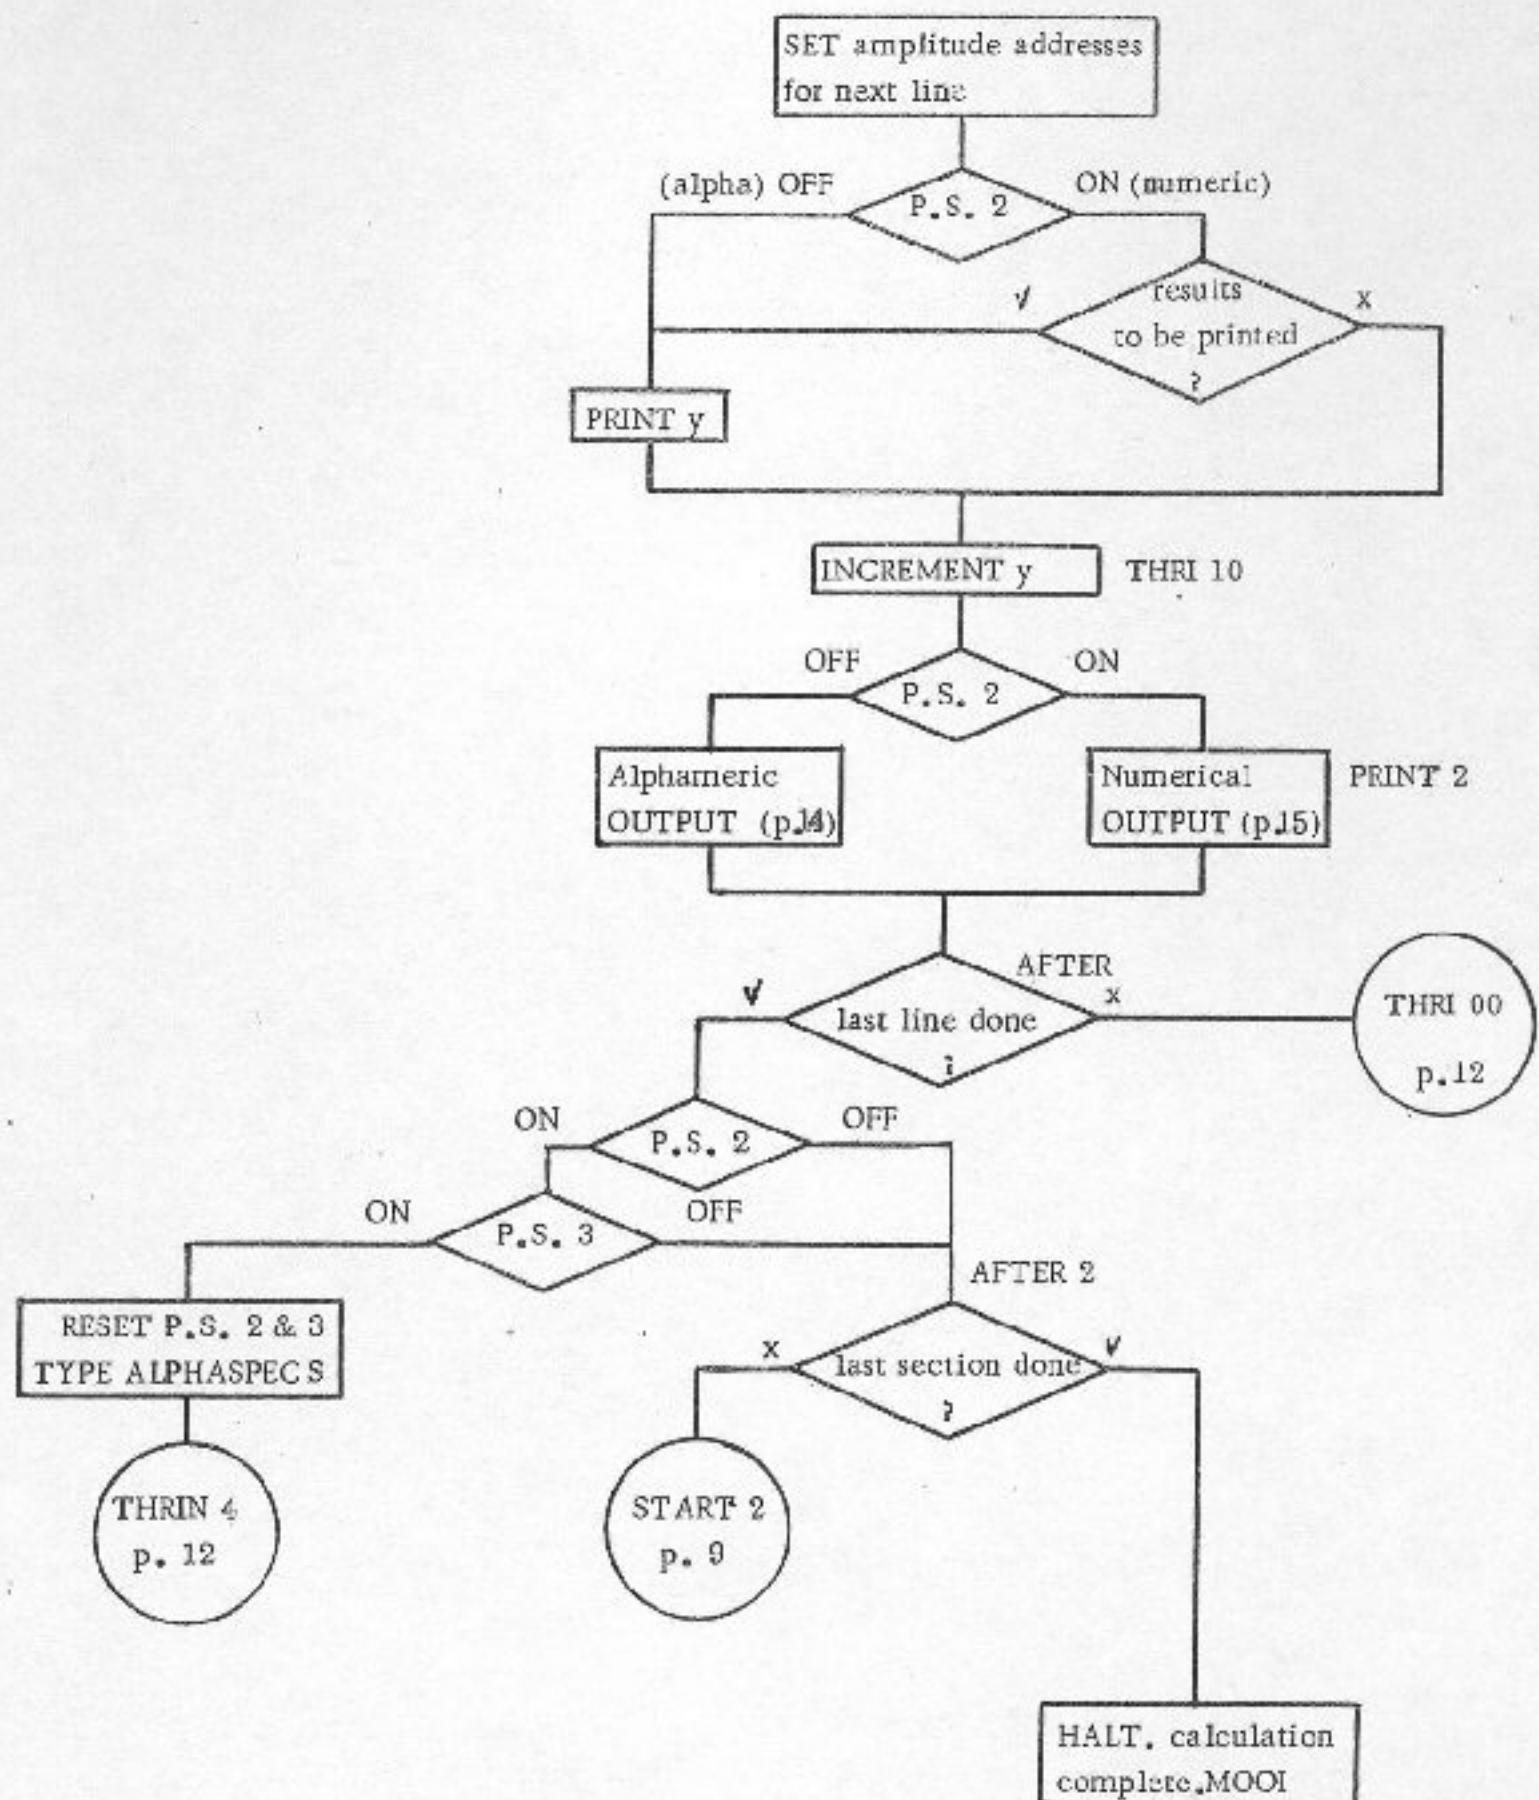

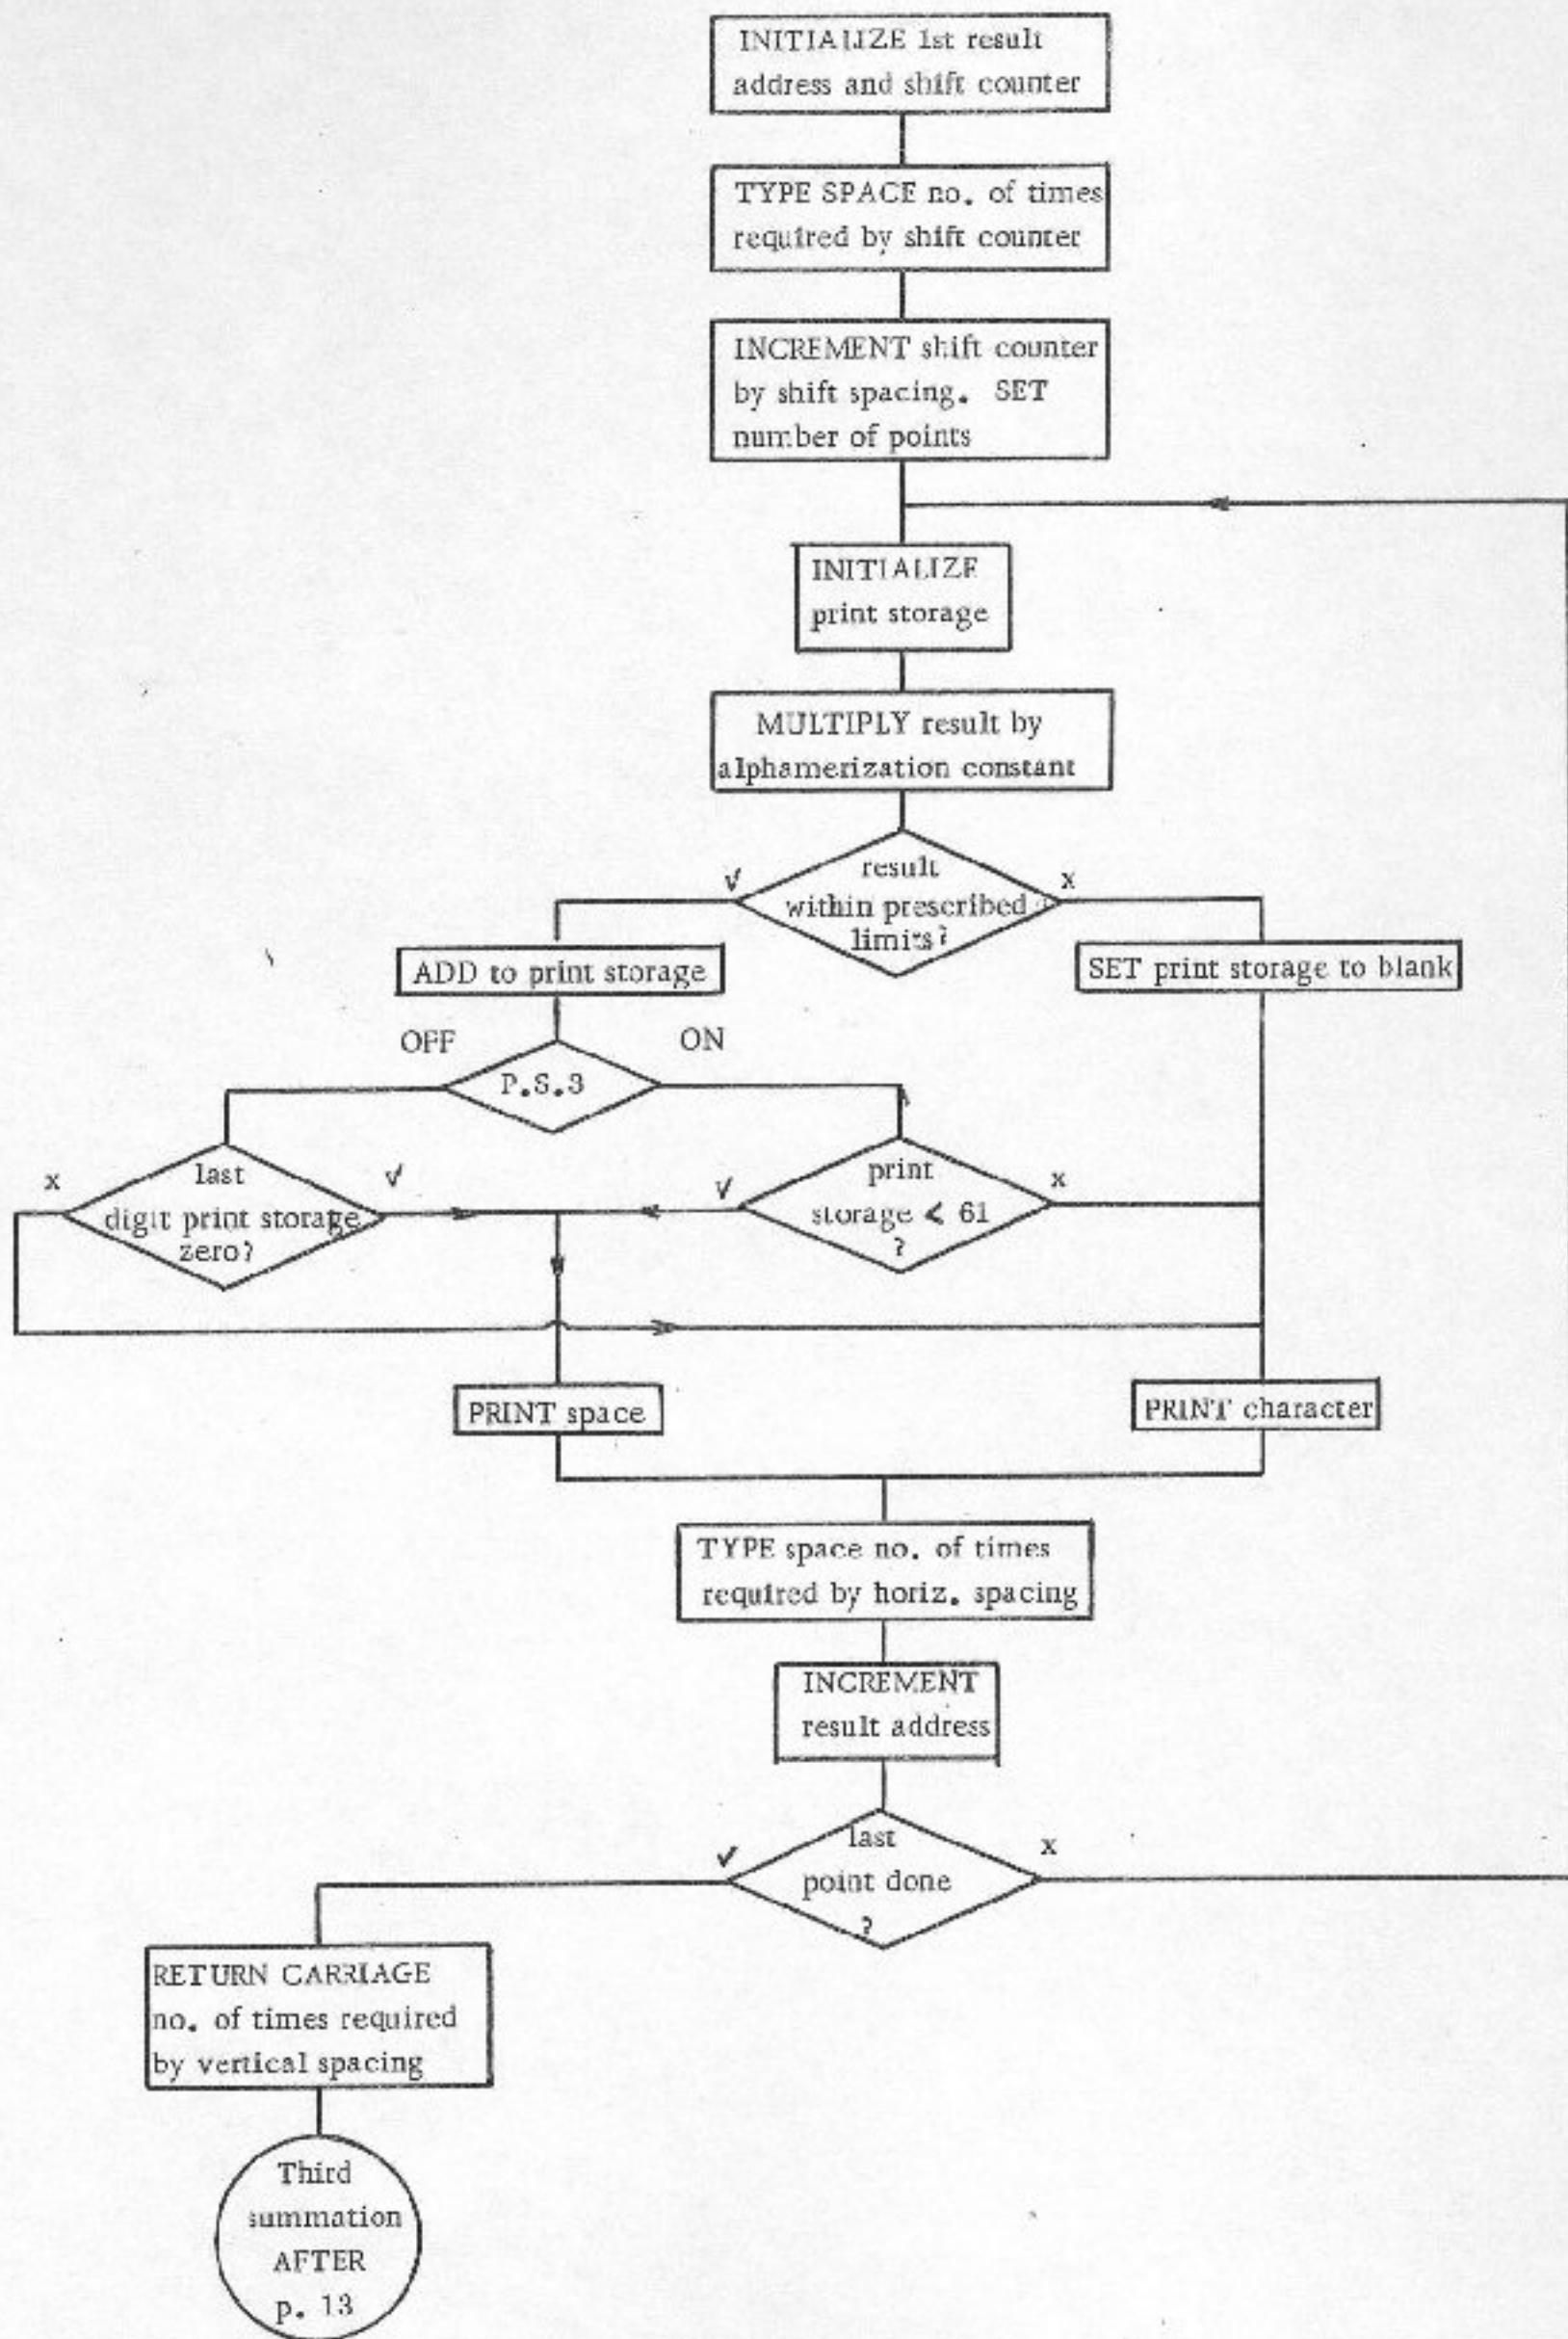

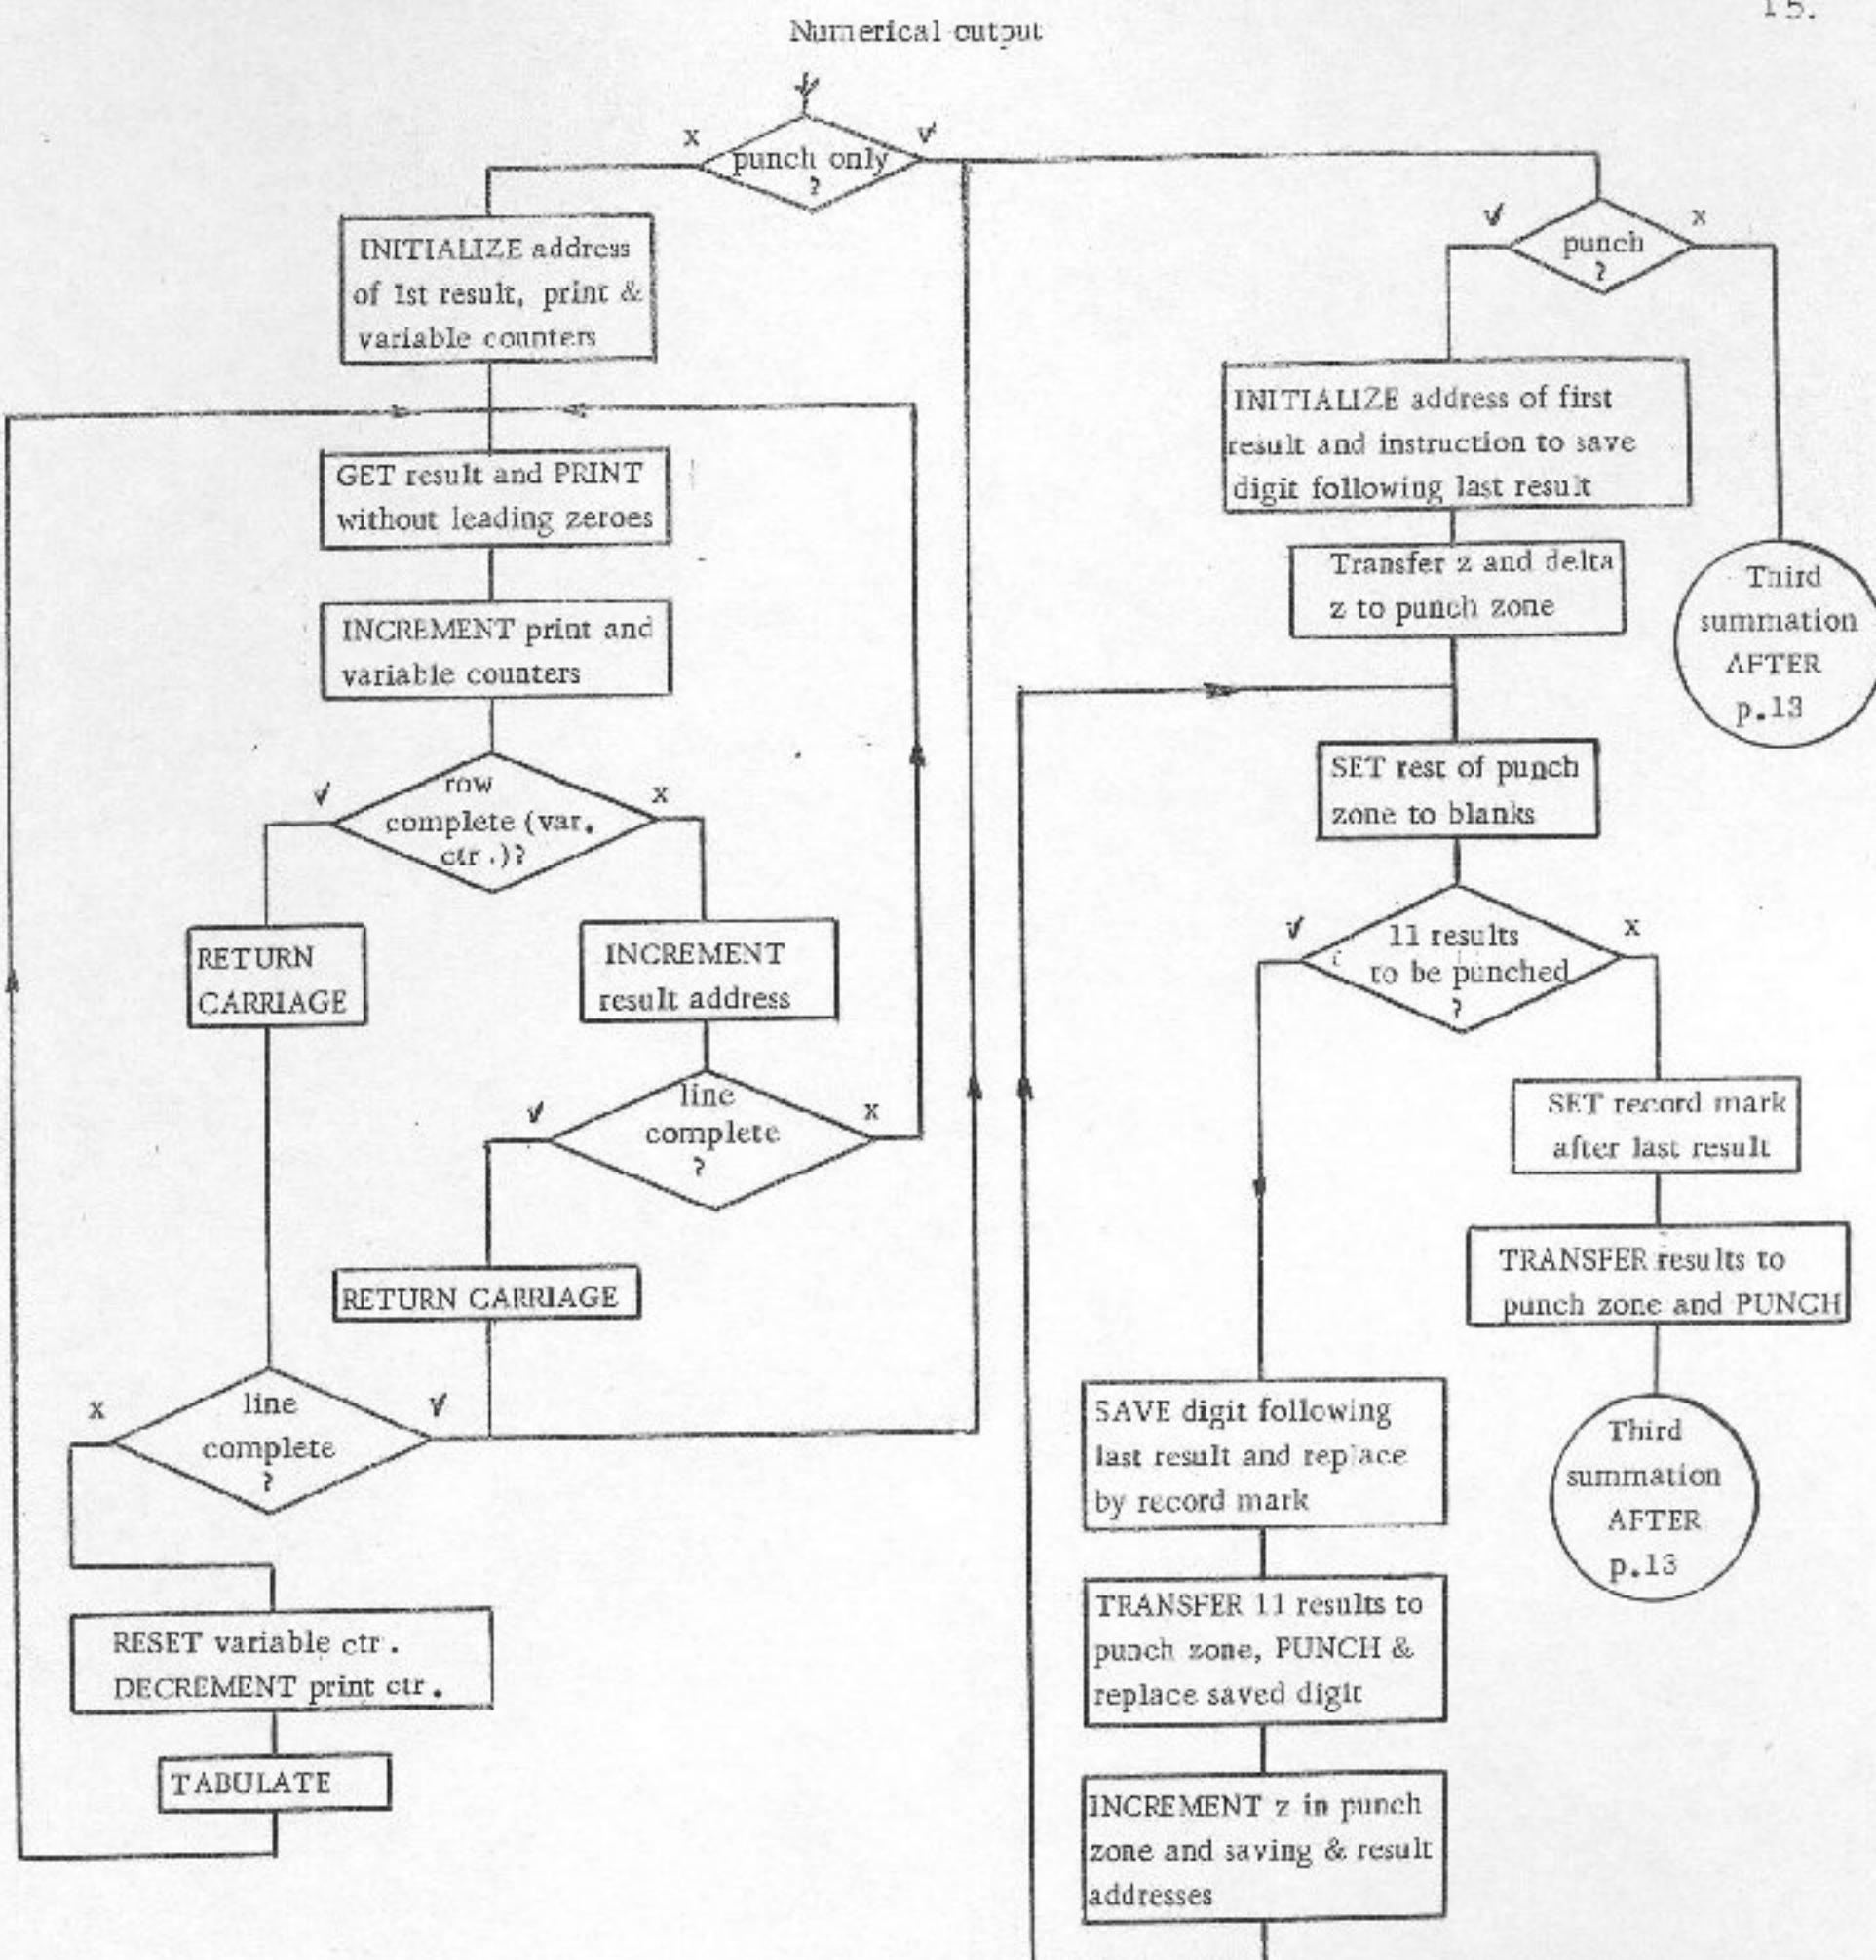

Subroutine used in second and third summations

IV. Input and Output

Note : All card zones of more than one column are X-punched in the left-most position.

Data. Each data card contains one hkl^i with its four (if centrosymmetric) or eight (if non-centrosymmetric) terms. The card format is :

Cols.	1 - 6	Identification code
	7 - 8	h }
	9 - 10	k } all positive
	11 - 12	l }
	13 - 16	A
	17 - 20	B
	21 - 24	C
	25 - 28	D
	29 - 32	E }
	33 - 36	F }
	37 - 40	G }
	38 - 44	H } blank if centrosymmetric

Negative values are denoted by an X-punch over the right-most position. The data cards must be sorted first on k, then on l.

The specifications of the summation may be introduced either via the typewriter or punched in a card. The following must be given. Identification code. The same six digit number as is punched in the data cards. A convenient system is to use the first three digits to represent the problem, the next two digits the run and the last digit 1, 2, or 3 according to whether observed, difference, or calculated data are being used.

1st, 2nd and 3rd sum minimum and maximum values. These are the bounds of the summation and will correspond to an integral number of hundredths of the unit cell edges. In the case of a projection both the first sum limits will be zero as will h.

1st, 2nd and 3rd sum delta are the increments (in hundredths of the unit cell edge) in each of the three axial directions. The last value calculated in each direction will be the largest that does not exceed the specified maximum. In the case of a projection the first sum delta will be zero.

1st, 2nd and 3rd sum shifts. The trigonometrical values are stored to four places of decimals so that, in order to conserve the position of the decimal point, it is necessary to eliminate four figures at each stage. By eliminating more or fewer figures it is possible to scale the results down or up during each summation. Thus the normal values will be 04 for all three shifts but values from 02 to 06 inclusive are possible. In order to reduce rounding errors it may be advantageous to have the input data ten times greater than

necessary and to make the third shift 05 in order to bring the results back to the correct scale. On the other hand it may be necessary to scale down by a factor of ten at some stage of the calculation to prevent overflow (see Error Indications below).

Horizontal, vertical and shift spacings are only called for if the program switches are set for alphabetic output. The first two of these may each have any value from 00 to 09 which are the number of blank spaces required between successive characters and the number of blank lines between successive rows. The shift spacing (09 to 09) is the number of additional spaces to be typed at the beginning of successive rows in order to give an oblique cell. A negative shift spacing corresponds to an obtuse angle β , a positive shift spacing to an acute angle β and a shift spacing of zero to an orthogonal cell.

Low and high limits of peaks are only called for if the program switches are set for alphabetic output. They determine the scale of the linear transformation used to convert each result P to the appropriate alphabetic character. This is $P'=41+38.(P-L)/(H-L)$ where L and H are the low and high limits called for by the programme. If P lies between L and H , P' will lie between 41 and 79 and will be printed as the corresponding alphabetic character (A-9) unless it is 50, 60 or 70 when a blank will be typed. A blank will also be typed if P is outside these limits. It is possible to suppress all values less than $(H+L)/2$ by use of program switch 3. If this is done, the value 70 will be printed as zero.

Symmetry. A 1 in this position causes the calculation of the contributions of terms E-H to be skipped. The corresponding zones of the data cards may be left blank. A 0 will cause the complete calculation to be carried out.

Output. If the program switches are set for numerical output, the typewriter will call for a one digit code which determines the output medium. If the code is flagged (0 or 1), the results will be printed and if it does not contain a digit (0 or 0) the results will be punched. Thus, when it is desired both to print and to punch, the code 0 will be used. The code 1 (no output) can be used to check that the shifts have been chosen so as to avoid overflow. This code does not affect the alphabetic output which can only be typed.

Number of answers in a row. With a 12" carriage typewriter there is space for up to 16 answers in a row of which the last will be repeated as the first of the following row (with the same y). It is perhaps more convenient to have 11 answers so that successive rows contain the results 0-10, 10-20, 20-30, etc.

The specification card format is :

Cols.	1- 6	Identification code
	7- 9	1st sum minimum value
	10-12	2nd sum minimum value
	13-15	3rd sum minimum value
	16-17	1st sum delta
	18-19	2nd sum delta
	20-21	3rd sum delta
	22-24	1st sum maximum value
	25-26	1st sum shift
	27-28	2nd sum shift
	29-30	3rd sum shift
	31	Symmetry
	32-33	Horizontal spacing
	34-35	Vertical spacing
	36-37	Shift spacing
	38-41	Low limit of peak
	42-46	High limit of peak
	47-49	2nd sum maximum value
	50-52	3rd sum maximum value
	53	Record mark

Even when alphameric output is not required, it is necessary to punch values for the low and high peak limits in order to prevent breakdown of the programme. During the introduction of numerical specifications via the typewriter, these values are automatically taken as -1000 and 10000.

Output format. Whatever the output medium, the identification code together with the third summation specifications will be typed as will the x-coordinate of each section calculated. In the case of typewriter output, the y-coordinate of each line is typed before the first row of each line. The number of numerical results per row or the format of alphameric results is determined by the specifications.

The format of the punched output is :

Cols.	1- 6	Identification code
	7- 9	x
	10-12	y
	13-15	z corresponding to first value on card
	16-17	Delta z
	18-21	
	22-25	
	'	
	'	
	'	
	58-61	Up to 11 four-figure values (last figure of negative values flagged) the last of which is followed by a record mark.
	62	

The eleventh value on a card will be repeated as the first value of the following card (provided that this card is necessary to complete the line of the synthesis).

v. Example

A part of the c-axis projection of 6-azidopurine will be calculated. The relevant plane group is pgg so that:

$$\rho_{xy} = \sum_h \sum_k \left\{ F(hk0) \cos 2\pi h x \cos 2\pi k y \cos 2\pi l z - F(hk0) \sin 2\pi h x \sin 2\pi k y \cos 2\pi l z \right\}$$

$\begin{matrix} h+k \text{ even} & \\ h+k \text{ odd} & \end{matrix}$

Thus for $h+k$ even, $F(hk0)$ is equal to the term A and for $h+k$ odd it is equal to the term B (see formula II, 2).

In the output we require as horizontal coordinate x (lines parallel to a) and vertical coordinate y. This implies a sequence of indices in each card of 0kh. According to table II, A and B must be placed in the first and fourth fields respectively so that the data cards have the following format :

Cols.	1- 6	000522 (identification code)
	7- 8	00
	9-10	<u>xx</u> k
	11-12	<u>xx</u> h
	13-16	xxxx A
	17-20	0000
	21-24	0000
	25-28	<u>xxxx</u> B
	29-80	blank

The cards must be sorted first on k then on h. The values of k, h, A, B used are listed in Table V.

a. We want to calculate the projection for $y = 0.28$ (0.01) 0.47 and $z = 0.00$ (0.02) 0.30 . The specifications are to be introduced via the typewriter so P.S. 1 is off. We require an alphamerical output with the peaks only so P.S. 2 is off and P.S. 3 on. The third sum shift is set at 05 to give a convenient output scale. We require one extra space horizontally between successive characters and no extra space vertically in order to obtain the approximate dimensions of the grid ($a = 11.72 \text{ \AA}$ and $b = 17.06 \text{ \AA}$). The shift spacing is zero as the grid is orthogonal.

From a previous calculation of this projection we know that the results lie roughly between -200 and +800. If we set h at 0200 and H at 00800 only the values above $(200 + 800)/2 = 300$ would be printed with P.S. 3 on so that a large, and possibly important, part of the peak would be suppressed. By setting L = 0550 all values above +125 are converted to an alphabetic character and printed.

The messages and results are shown in Fig. Va.

b. The second example is a numerical print-out (P.S. 2 on) of the same part of the projection. The only difference is that the interval along the y-axis is taken as 0.02 instead of 0.01 so that the greatest value of y calculated will be 0.46 ($0.28 + n \cdot 0.02$) instead of 0.47. As we only require the numerical output, P.S. 3 should be off.

The messages and results of this example are shown in Fig. Vb.

VI. Operating Instructions

1. Set typewriter margins at 10 and, on a 12" machine, 96. Set tabs at 14, 15 and 50.
 2. Set parity, I/O and overflow check switches to STOP. Set P.S. 1 ON if the specifications are to be entered via a card, OFF if they are to be typed. Set P.S. 2 OFF if alphabetic output only is required in which case P.S. 3 should be OFF to print characters A-9 and ON to print characters /-9 and blanks instead of A-R. Set P.S. 2 ON if numeric output is required in which case P.S. 3 should be ON if this is to be followed by alphabetic output otherwise OFF. Set P.S. 4 OFF.
 3. Clear machine storage to zeroes.
 4. Load the programme into storage, press START and follow the messages typed. The figures in parentheses at the end of some messages indicate the number of digits to be typed by the operator. All messages except the following have been described in the section on input.
 5. Message SET P.S. 2, 3 TYPE ALPHASPECS is printed on completion of the numerical output of each section when P.S. 2 and 3 are both ON. Set P.S. 3 OFF and P.S. 3 as required to give either the full alphabetic results (OFF) or only the highlights (ON). Type ~~xxxxxx~~ (RS) where the first three fields are the horizontal, vertical and shift spacings, and the last two are the low and high peak limits. A typing error may be corrected before (RS) is typed by pressing RESET, INSERT and typing 4904378 (RS). LOAD DATA will be printed at the end of each section except the last. Set P.S. 3 and 3 ON again before pressing start. Although SET P.S. 2, 3, TYPE ALPHASPECS is printed after each section, the constants, once introduced, remain unchanged and it is only necessary to type (RS) on subsequent occasions.
 6. Message MOOI is printed on completion of the last section.
 7. Error Messages. There are six different errors indicated by the machine's typing ER n and halting. Depression of the START key will cause a MAR check. The codes are :

ER 1 - A data card has an identification code different from that of the specifications.

ER 2 - Card out of sequence with respect to 1.

ER 3 - Card out of sequence with respect to k in a particular group 1.

ER 4 - Overflow during the first summation ; the first sum shift constant should be increased by unity.

ER 5 - The second summation results require more space than is available ; reduce the number of lines to be calculated.

ER 6 - The second and third summations overlap one another ; reduce the number of lines to be calculated.

ARITH CHK. If an overflow occurs between the printing of LOAD DATA and of SECTION xxx the second sum shift constant must be increased by unity. If the overflow occurs after SECTION xxx has been printed the third sum shift constant should be increased.

It is desirable to verify that the overflow is due to an incorrect choice of shift constant rather than to some other cause such as a field-defining X-punch missing from a data card (which can be checked by eye). The following procedure should be followed when the 1620 stops on ARITH CHK :

1. Set the Memory Address Register Display Selector to IR-1 and press RESET, DISPLAY MAR. The Memory Address Register (MAR) should read 01938 which is the address of the instruction in the Subroutine following the accumulation instruction which caused the overflow.
2. Set the MAR Display Selector to IR-2 and press DISPLAY MAR. The MAR should now indicate 01522 or 02914 for second or third summation overflows respectively.

After making the appropriate correction it is necessary to reintroduce the programme.

8. Other possibilities of error. Two other types of error are possible, neither of these has ever been known to occur. The first is an overflow of one of the temporary storages during the first summation. As these have ten digits and the maximum contribution of one term is 99980001 (amplitude 9999 x trigonometric function 9999) this would require at least 101 values in one group kl. If this were to happen, the contents of IR 1 after ARITH CHK would be 01142.

The second error could only occur when a shift of 03 or 02 is used in the second or third summation. In these cases the one or two most significant digits of the product are cut off by a Set Flag instruction. If these digits are not zero, an incorrect value will be accumulated without any indication of error. However, it is most improbable that this will happen without the next most significant digits being sufficiently large to give overflow on accumulation of two or more values. For this reason an extra test to check for digits so lost has been omitted as it would increase the running time of the most frequently used block of the programme.

VIII. Maintenance

The core layout is as follows :

00020-00057	Specifications
00100-00400	Arithmetic tables
00402-04459	Programme
04460-05359	Trigonometric tables
05360-05601	Constants and working storage
05602-19989*	Storage for second and third summation results
19990*-19999*	Working storage used in scaling and rounding off
15001-18316	Initialization programme.

Addresses marked * are given for a 20K machine. Processing the symbolic programme for a larger machine will cause these addresses to be augmented. There is no space available for modifications to the programme unless the size of the second summation is limited when space will become available up to location 19585*. Such limitation could be achieved by modifying the instruction at 01578 to 14 01620 xxxx where xxxx + 1 is the beginning of a patch.
