## Contents

- I General Theory
- II Format of Input and Output
- III Operation
- IV Example
- V Program Listing
- VI Flow Sheets

The program (identification number 043001) is written for the I.B.M. 1620.

Memory: 20,000 digits

Input: Paper tape

Output: a. 12" carriage typewriter

b. 20" carriage typewriter (the latter is not absolutely necessary  
but allows for more freedom in the format of the output)

c. Tape

Limitations of the Program: See Section I

Timing: See Section I

Cells of the Program:

00029 - 00079	working storage
00100 - 00399	multiplication and addition tables
00402 - 00451	working storage
00452 - 00473	read-area
00474 - 00539	working storage
00540 - 05100	program
05100 - 05999	ccsine and sine table
06000 - 19479	storage for 1st and 2nd summation answers
19495 - 19999	storage for 3rd summation answers
10000 - 13750	initialization program

Hash Total: 67058544165826702962

Duplicating: Use the IBM library program: 1620 Numeric Tape Duplicator/Corrector.

Fournier Example 622 909 784 700 595 447 26

## I. General Theory

The electron density can be evaluated at each point,  $x, y, z$  of the unit cell by the formula

$$\rho(x,y,z) = \frac{2}{V} \sum_{h=0}^{\infty} \sum_{k=-\infty}^{\infty} \sum_{l=-\infty}^{\infty} A'(hkl) \cos 2\pi (hx + ky + lz) + B'(hkl) \sin 2\pi (hx + ky + lz) \quad (I,1)$$

To calculate a Fourier with this formula proves to be very uneconomical with respect to the computing time involved. In a practical example of a centrosymmetric space group with 2000 Fourier coefficients in which 25 points in the  $x$ - and  $y$ -direction and 50 points in the  $z$  direction have to be calculated, it would take the I.B.M. 1620 about 140 hours to perform the calculations (not including the typing out).

It is possible to rewrite formula I,1 (Lipson and Beevers) in the form:

$$\rho(xyz) = \frac{2}{V} \sum_{l=0}^{\infty} \left[ \sum_{k=0}^{\infty} \left( \sum_{h=0}^{\infty} A(hkl) \cos 2\pi hx + E(hkl) \sin 2\pi hx \right) \cos 2\pi ky + \left( \sum_{h=0}^{\infty} F(hkl) \cos 2\pi hx + B(hkl) \sin 2\pi hx \right) \sin 2\pi ky \right] \cos 2\pi lz + \left[ \sum_{k=0}^{\infty} \left( \sum_{h=0}^{\infty} G(hkl) \cos 2\pi hx + C(hkl) \sin 2\pi hx \right) \cos 2\pi ky + \left( \sum_{h=0}^{\infty} D(hkl) \cos 2\pi hx + H(hkl) \sin 2\pi hx \right) \sin 2\pi ky \right] \sin 2\pi lz \quad (I,2)$$

in which:

$$A = F(hkl) + F(\bar{h}\bar{k}\bar{l}) + F(h\bar{k}\bar{l}) + F(\bar{h}k\bar{l}) \quad I,3$$

$$B = -F(hkl) + F(\bar{h}\bar{k}\bar{l}) + F(h\bar{k}\bar{l}) - F(\bar{h}k\bar{l}) \quad I,4$$

$$C = -F(hkl) + F(\bar{h}\bar{k}\bar{l}) - F(h\bar{k}\bar{l}) + F(\bar{h}k\bar{l}) \quad I,5$$

$$D = -F(hkl) - F(\bar{h}\bar{k}\bar{l}) + F(h\bar{k}\bar{l}) + F(\bar{h}k\bar{l}) \quad I,6$$

In noncentrosymmetric space groups:  $F(h_i) = A(h_i)$  and:

$$E = B(hk\ell) - B(\bar{h}k\ell) + B(h\bar{k}\ell) + B(h\bar{k}\bar{\ell}) \quad I,7$$

$$F = B(hk\ell) + B(\bar{h}k\ell) - B(h\bar{k}\ell) + B(h\bar{k}\bar{\ell}) \quad I,8$$

$$G = B(hk\ell) + B(\bar{h}k\ell) + B(h\bar{k}\ell) - B(h\bar{k}\bar{\ell}) \quad I,9$$

$$H = -B(hk\ell) + B(\bar{h}k\ell) + B(h\bar{k}\ell) + B(h\bar{k}\bar{\ell}) \quad I,10$$

A, B, ..., H, should include a multiplicity factor.

The form (I,2) cuts the number of arithmetic operations by about a factor of 15. The logic however, and therefore the computer program, becomes more cumbersome and less clear. In fact it cuts the calculation up in three different parts, which are consecutive summations over each of the three axes.

Definition: We call a set of terms, A, B, C, ..., H, with the same indices  $h$ ,  $k$  and  $\ell$ , an amplitude.

In the first summation over  $h$ , sums are made of terms, which have different index  $h$ , but the same indices  $k$  and  $\ell$ . Pairs of sums are added together as shown in formula I,2.

Definition: Each group of amplitudes for which the indices  $k$  and  $\ell$  are the same is called a "group  $\langle k\ell \rangle$ ".

Thus sums are calculated (and pairs of sums) for each group  $\langle k\ell \rangle$  and for all needed values of  $x$  in the first summation.

The difficulty which occurs will be clarified by an example. We want to make a Fourier synthesis with 1500 amplitudes, which are sorted in 250 groups  $\langle k\ell \rangle$ . We want to calculate 26 sections on  $x$  (values of  $x$ ). Each group  $\langle k\ell \rangle$  gives rise to four sums (formula I,2) for each value of  $x$ . The total number of sums is therefore going to be  $(250) \cdot (4) \cdot (26) = 26,000$  sums. The first possibility is to store all sums inside the computer. In the preceding example that is clearly impossible, and in general one should put severe limitations on the scope of the program.

The second possibility is to store the sums on paper tape, which makes a sort of the sums necessary. A sort with paper tape is however impractical and slow.

The third possibility, which is the one we choose, is to calculate in the first summation stage only for one value of x at a time. In other words to calculate only one section at a time. It is easily possible to store these sums (in the example:  $(4).(250) = 1000$  sums) inside the computer.

The disadvantage of this approach is of course the fact that for each new section the data tape with amplitudes has to be fed in again. Reading paper tape is however much faster than punching data (10 times), which means that this method is (much) more economical in time (for this computer) than calculating the complete first summation all at once.

The calculations and results of the first summation stage are in this case:

$$M(k\ell X) = \sum_{h=0}^{\infty} A(hk\ell) \cos 2\pi hX + E(hk\ell) \sin 2\pi hX \quad (I,11)$$

$$N(k\ell X) = \sum_{h=0}^{\infty} F(hk\ell) \cos 2\pi hX + B(hk\ell) \sin 2\pi hX \quad (I,12)$$

$$O(k\ell X) = \sum_{h=0}^{\infty} G(hk\ell) \cos 2\pi hX + C(hk\ell) \sin 2\pi hX \quad (I,13)$$

$$P(k\ell X) = \sum_{h=0}^{\infty} D(hk\ell) \cos 2\pi hX + H(hk\ell) \sin 2\pi hX \quad (I,14)$$

in which X is a definite value of x.

These sums are stored with four digits each, while k and  $\ell$  are stored with two digits each, inside the computer. One set of sums (from one group  $\langle k\ell \rangle$ ) therefore occupies 20 digits of memory (thus using the variable word length feature of the computer to great avail). They are stored up to memory location 19479. During initialization the program calculates where to store the first set of sums (that is in location 19480 -  $\langle k\ell \rangle .20$ ). A value for the total number of groups  $\langle k\ell \rangle$  has thus to be known beforehand.

Definition:  $\langle k\ell \rangle$  = total number of "groups  $\langle k\ell \rangle$ ".

Preferably one likes to reuse the storage area occupied by these first summation answers. In what way that is possible is discussed in the next few paragraphs.

The second summation uses the answers of the first summation as amplitudes and performs the following calculations: (See also I,2)

$$R(\ell, X, y) = \sum_{k=0}^{\infty} M(k\ell X) \cos 2\pi ky + N(k\ell X) \sin 2\pi ky \quad (I,15)$$

$$S(\ell, X, y) = \sum_{k=0}^{\infty} O(k\ell X) \cos 2\pi ky + P(k\ell X) \sin 2\pi ky \quad (I,16)$$

The summations are over k. Sums are made from sets of amplitudes ( $M, N, O, P$ ) with the same  $\ell$  ( $X$  is a definite value and thus for all amplitudes the same). The answers are two sums for each value of  $y$  and each value of  $\ell$ .

Definitions:

$N_y$  is the number of points calculated in the y-direction

$N_z$  is the number of points calculated in the z-direction

When  $\ell$  changes the  $2 \cdot (N_y)$  sums:  $R(\ell, X, y)$  and  $S(\ell, X, y)$  are stored in memory locations 06000 and up (4-digits each), and the calculation proceeds with the next series of sets of amplitudes.

It appears useful to have all sets of amplitudes ( $M, N, O, P$ ) with the same value of  $\ell$  stored together. If the sets with  $\ell=0$  are stored in the beginning of the storage area used for first summation answers, and if the ones for  $\ell=1$  and  $\ell=2$ , etc., follow consecutively, it is possible to use this memory space again for the storage of the second summation answers, because first summation answers, after being used as amplitudes in the second summation, are allowed to be erased.

This procedure is followed and is the main principle of the program, and it enables us to use the memory space between 06000 and 19479 for 1st and 2nd summation answers both.

This does however imply a sorting order on the data tape. It is clear that in the consecutive amplitudes on the data tape the  $\ell$  should change the least (in order to obtain the 1st summation answers in the necessary array) and that the  $h$  should

change the most, because the first summation is over  $h$ . That is a sorting order  $\bar{h}\bar{k}\bar{\ell}$ :  
 $0,0,0; 1,0,0; \bar{h},0,0; 0,1,0; h,1,0; h,k,0; 0,0,1; 1,0,1; \bar{h},0,1; h,k,1; h,k,\ell$ . (See also Sections II and IV.)

The third summation calculates:

$$\rho(x,y,z) = \sum_{\ell=0}^{\infty} R(\ell,x,y) \cos 2\pi \ell z + S(\ell,x,y) \sin 2\pi \ell z \quad (\text{I},17)$$

using the second summation answers as amplitudes.

The procedure of the program is to calculate  $N_z$  sums for one value of  $y$  (line  $y = \text{constant}$ ) at a time, and the  $N_z$  answers are typed or punched out line after line.

The manner in which the memory between locations 06000 and 19479 is used for first and second summation answers indicates the limitations of the program. Neither summation can occupy an area larger than 13480 digits.

For the first summation this means a limitation on the maximum number of groups  $\langle k\ell \rangle$  namely:

$$\langle k\ell \rangle_{\max} \leq 13480/20 = 674 \quad (\text{I},18)$$

For the second summation it means a limitation on the maximum value of  $( = L_{\max})$  and  $N_y$ , namely

$$(N_y \cdot L_{\max}) \leq \frac{13480}{8} = 1685 \quad (\text{I},19)$$

The program will stop and type out ER2, when a momentary overlap occurs of first and second summation answers. That is when an attempt is made to store second summation answers in an area in which first summation answers are stored which are not yet used as amplitudes in the second summation.

It is not felt that the limitations are serious. In some cases the limits might be a few percent smaller. They are only exact when

$$20 \cdot k_{\max} = 8 \cdot N_y \quad (\text{I},20)$$

in each series of  $\ell$ .

The approximate computing times for an example with 1500 amplitudes calculating a section of 25 by 50 points is given below with the main factor determining the computing time in each stage:

		due to :
Reading	220 sec	no. of amplitudes
1st summation	71 sec	$\langle k\ell \rangle$
2nd summation	277 sec	$\langle k\ell \rangle \cdot N_y$
3rd summation	480 sec	$\langle k\ell \rangle \cdot N_y \cdot N_z$
Typing	680 sec	$N_y \cdot N_z$

The program can just as well be used for an  $F^2$ -synthesis of course.

## II. Format of Input and Output

In the preceding section it was supposed that the first summation was over  $h$ , the second over  $k$  and the third over  $\ell$ , implying the sorting order  $h\vec{k}\ell$  and implying sections  $X = \text{constant}$ .

It is however preferred to have more freedom in arranging the data and three reasons can be named.

- a. The ability to make sections in other directions.
- b. It might be necessary to sum in another order for instance when a programmed stop occurs (ER2 was mentioned in Section I).
- c. Another order of summations might also be preferred in view of the computation time (see timing table in Section I).

For convenience a conversion table is made: Table II, A.

The data tape. Indices are punched with two digits each, terms A-H with four digits each. Each amplitude is followed by a record mark (R.M.). For centrosymmetric space groups one punches only the terms A-D, and the fourth term is followed by a R.M. The first record on the tape has to be an identification (arbitrary number of digits) of the data tape, followed by a R.M. The last record should be any 6-digit number followed by a R.M.

We have written a program (partly checked out), which prepares the data tape (called S.F. - F.S. program). It takes the paper tape output of the structure factor program, sorts the amplitudes in the desired sorting order, combines the structure factor amplitudes to terms (A-H) and arranges the terms according to the sorting order. The synthesis can be brought on absolute scale by including  $F(000)$  as term (A), and by multiplying the terms by the factor  $2/V$  beforehand.

The output is either on the typewriter or on the typewriter and paper tape. In general one would use only typewriter output.

Typewriter. The sorting order is equivalent to the order of summation. The first index determines therefore on which axis the sections are. The second index determines the vertical and the third index the horizontal coordinate of the

sections in the typewritten output. The output is preceded by several alphanumeric headings and by one line of numbers, the last being identifications of the specification tape (see Section III), program tape and data tape respectively. The possible choices of the manner in which the answers are typed are described in Section III.

Paper tape. It is possible to punch all density maps out on paper tape together with the typewritten output, thus making a copy of the results on tape. The numerical answers of each section are preceded by the number of the section and each line of answers in the section is preceded by the number denoting the line. Each separate number is followed by a R.M. In the tape output the answers are preceded by the following records: a) identification of the specifications, b) specifications (see Section III), c) identification of the program tape, and d) identification of the data tape.

Projections are calculated as sections. The first index should always be zero (see Table II, A).

Conversion Table II, A

Sorting order	Terms	Sections or	Vertical coordinate	Horizontal coordinate
Indices	3-Dimensional			
$\vec{h} \vec{k} \vec{\ell}$	A B C D   E F G H ≠	x	y	z
$\vec{k} \vec{h} \vec{\ell}$	A B D C   F E G H ≠	y	x	z
$\vec{k} \vec{\ell} h$	A D B C   F G E H ≠	y	z	x
$\vec{h} \vec{\ell} k$	A C B D   E G F H ≠	x	z	y
$\vec{\ell} \vec{h} k$	A C D B   G E F H ≠	z	x	y
$\vec{\ell} \vec{k} h$	A D C B   G F E H ≠	z	y	x
	Input		Output	
	Projection			
$\vec{o} \vec{k} \vec{\ell}$	A O O D   O F G O ≠	-	y	z
$\vec{o} \vec{h} \vec{\ell}$	A O O C   O E G O ≠	-	x	z
$\vec{o} \vec{\ell} h$	A O O C   O G E O ≠	-	z	x
$\vec{o} \vec{\ell} k$	A C O D   O G F O ≠	-	z	y
$\vec{o} \vec{h} k$	A C C B   O E F O ≠	-	x	y
$\vec{o} \vec{k} h$	A C C B   O F E O ≠	-	y	x
	Input		Output	

Possible arrangements of the indices on a data tape with their implied sorting order and arrangement of terms, and the format of the typewritten output belonging to it.

III. Operation

- a. One can discern the following stages during the operation
  1. Loading of the program tape.
  2. Tape feeding or typing of the specifications of the summation and the output.
  3. Loading of the data tape.
  4. Calculating and typing (and taping) of the results of one section.
  5. If it was specified in 2. that more than one section had to be calculated: reloading of the data tape and returning to 4. If it was a projection or the last section: halting.

b. Switch settings

Parity : Stop

Input/Output : Stop

Overflow : Stop

Program Switch 1 : On

(When off it will type out all the answers of the first summation in unrounded and unshifted form. Can be used for checking.)

Program Switch 2 : See Section III d, 6, 8.

Program Switch 3 : See Section III d, 8.

Program Switch 4 : See Section III d, 1, 12.

c. Manual Operations

1. Clearing Memory: Insert; Key in : 16 00010 00000; Release; Start.

After clearing: Stop SCE; Reset.

2. Ready Tape Reader with program tape.

3. Loading of program tape : Insert; Key in : 36 00000 00300;  
Release; Start.

4. Almost at the end of the program tape the loading will stop :  
Press Start.

5. Follow instructions of the messages which are typed out. Always press Release and then Start after typing a specification in.

d. The remainder of this section is an explanation of some of the messages which are typed out. The number in parentheses after each message tells how many digits there are in the number and which have to be typed.

1. Message

"When specs are typed set S.W. 1 off. From tape S.W. 1 on."

In general the specifications of the summation will be typed in. In that case S.W. 4, that is Program Switch 4, should be off. It is however possible to prepare the specifications on tape beforehand. For the preparation of such a tape see Section III d, 12.

2. Message

"Type ident of specs tape now made."

It is necessary to type in a 6-digit number. The number itself is arbitrary but can be useful in a identification scheme.

3. Messages:

"Type 1st sum min."

"Type 1st sum max."

"Type 2nd sum min."

"Type 2nd sum max."

"Type 3rd sum min."

"Type 3rd sum max."

"Type 1st sum delta"

"Type 2nd sum delta"

"Type 3rd sum delta"

These determine the amount of the unit cell to be calculated and the grid spacing.

All are in hundredth of the cell edge. Furthermore:

$\frac{n \text{ th sum max} - n \text{ th sum min}}{n \text{ th delta}} = p$ , in which p should be an integer.

The first and the final section are determined respectively by the values of "1st sum min" and "1st sum max." The interval of the sections between the final and the first are determined by "1st sum delta." For a projection the value of "1st sum min" should be typed equal to the value for "1st sum max" and 1st sum delta should be 00.

Similarly the remainder of the values to be typed in determine the part of the sections which needs to be calculated. The allowed range of the values belonging to the first 6 message are from 000 up to 100 and for the last three from 00 up to 98.

Any bloc of the unit cell can be calculated, and it is also possible in the same manner to calculate just one specified point in the unit cell.

#### 4. Messages

"1st sum shift"

"2nd sum shift"

"3rd sum shift"

The program uses a table of cosine and sine values. The table contains 100 values of each and each having four decimal digits after the decimal point. The basic calculation of the Fourier summation is either:  $Q_j \cos h_i x_p$  III,1  
or:  $Q_j \sin h_i x_p$  III,2

The values  $h_i$  are integers, and the values  $x_p$  always have two decimal digits after the decimal point. Therefore a table of 100 cosine and sine values is sufficient and a straight table look up can be used without interpolation.

The program accepts and works only with fixed decimal numbers, and it is therefore necessary to keep track of the decimal point.

The normal shift after a calculation of the type III,1 or III,2 is four places, due to the four decimal digits of the values in the trigonometric table. Thus typing in 04 for each of the three shift values will keep the decimal point in the answer at the same place as in the terms on the data tape (counted from the right of course).

Normally type 04 for each.

It might happen however that there is an accumulation in a particular sum which gives rise to an overflow (the machine will stop because O-flow is on Stop). One has to restart the calculation by reloading the program tape and changing one of the three shift values (it is of course not necessary to recalculate the sections which are already finished).

It is necessary to consider which shift order has to be changed. There are three possibilities

- i. There was a type out: ER. 3. This means an overflow in the 1st summation and therefore "1st sum shift" should now be typed in as 05 instead of 04. If not check I.R. 1 (by putting Display at I.R. 1, and pressing Reset and Display Mar) It should have 02646. If not there is a programming error.
- ii. Change 2nd sum shift: from 04 to 05 when the message "Horiz. Indcx" is not yet typed out.
- iii. Change 3rd sum shift from 04 to 05 when this message: "Horiz. Index" has been typed out.

It is not likely but indeed possible that an overflow will occur even after a change in one of the shift values is made. The summation in which it happened can again be tied down in the manner described above.

On the other hand it is possible that one would like to have the answers with one more digit after the decimal point. This can be achieved most effectively by changing the value of the 1st sum shift from 04 to 03, but can also be done in either of the other summations.

Shift values 02, 03, 04, 05 and 06 can be used in each summation.

#### 5. Message:

"Type in number of answers on a row."

This message will be typed out when P.S. 2 is on. With P.S. 2 on the output will be in numerical form.

With a normal length typewriter carriage it is generally impossible to get all  $N_z$  (see Section I) values for one line,  $y = \text{constant}$ , on one horizontal row. The program is normally set for 16 numerical answers on one row. The first answer on the next row will be a repeat of the last answer on the former row, giving a fairly regular array with multiples  $z_{\min} + \Delta z .15$  below each other on the first vertical line of answers.

Thus type in normally: 016. However any other number can be typed in. Typing in 011, will result in listing the answers with multiples  $z_{\min} + \Delta z .10$  below each other on the first line.

#### 6. Message

"Output. Type only =1. Tape and type =0."

As was mentioned before, it is possible to make a paper tape copy of the numerical results of the calculation, which may later be used for peak analysis or in the case of a  $F^2$ -synthesis, for a superposition procedure. Part of the paper tape output is the specification record, which holds such parameters as were described in Section III d, 3. These summation parameters, determine exactly the array of numbers of the paper tape: general specifications, section identification, line identifications and results.

#### 7. Messages

"Type horiz. spacing"

"Type vert. spacing"

"Type shift spacing"

"Type high limit of peaks"

"Type low limit of peaks"

These messages will be typed out when program switch 2 is off. When P.S. 2 is off the output will be in alphanumeric form.

In order to save the time consumed by plotting manually the numerical answers on the grid of the unit cell, a direct plotting system was devised on an approximate grid.

For this purpose each four digit numerical answer is translated into a one digit alphanumerical answer.

The first three messages. The relative dimensions of the grid can be approached as closely as possible by spacing horizontally (between the one digit answers) and vertically (between the lines). Typing in 00 is interpreted as the normal spacing of the typewriter either horizontally or vertically. Typing 01 will result in one extra space between either the one digit answers or the lines. Similarly 02 will result in two extra spaces etc. An askew cell instead of a rectangular one can be approximated by shifting (0C, C1, or more spaces) the next line with respect to the former one. For a rectangular cell type in 00. For an askew cell type in 01, 02 or more. (The 20" carriage can be very useful in this respect. By changing a few program orders it is possible to shift a line every other line or even less.)

The last two messages. Used as one digit answers are: 41 (=A) up to 79 (=alphanumerical 9). There are thus 39 different answers possible. The characters 50 and 60 are always printed as a space (blank).

If the answers go up to +9999, and down to -9999, one has to type in for the high limit (=E): 09999 and for the low limit (=L): 9999. It is then necessary to bring all answers in between -9999 and +9999 into the range from 41 to 79, which is of course possible by using a proper scale and base factor (both of which are calculated by the program). In this case an answer P is brought into this range in the program by means of:

$$\frac{P-L}{H-L} \cdot 39 + 41 = \frac{P-(-9999)}{19998} \cdot 39 + 41$$

III,3

and so is any answer  $9999 \leq P \leq -9999$ .

If the highest answer is 1000 instead of 9999, and the lowest -1000 instead of -9999, only a small part of the possible range should be used in fact only from Q-S, when H was put to +9999 and L put to -9999. In this way all detail in the Fourier might get lost.

It is therefore made possible to type in any high and low limit (with no more than 4 digits). It is not necessary that all the answers fall within the limits. If an answer is outside the limits, the program will insert and type a blank.

### 8. The use of Program Switch 3.

#### i. When P.S. 2 is off.

That is in the alphanumerical output. In the direct alphanumerical plotting of a Fourier it is sometimes clarifying to show only the peaks and to suppress the printing of the base level of a Fourier. This can be achieved by setting P.S. 3 on when P.S. 2 is off. The result of this setting is that the printing of all characters below 60 (A up to R) is suppressed and a blank (space) is printed instead. In other words all answers below  $\frac{H+L}{2}$ , will not be printed.

By proper use of H, L and P.S. 3 one has a great variety of alphanumerical outputs.

When P.S. 3 is on, the character 70 is printed as a zero. When P.S. 3 is off it is transcribed as a space (as are 50 and 60).

These spaces (50,60,70) might possibly be used as contour lines, although we have not had much success with this as yet.

#### ii. When P.S. 2 is on.

That is in the numeric output. When one does a projection it is sometimes quite impossible to guess what the upper and lower limits are. Of course one might do the projection first numerically, then reload the program and recalculate the projection alphanumerically. It is however possible to repeat only the third summation, without reloading the program.

When program switch 2 and 3 are both set on, the computer will stop after the numerical output is finished and type out the message:

"Set P.S. 2,3. Type alphaspecs."

One has then to set P.S. 2 to off (for alphanumeric output) and P.S. 3 to choice (see Section III d, 7, 8i) and has to type in three 2-digit, one 5-digit, and one 4-digit numbers (with flags over the left-most digits of each number), which are respectively; horizontal space, vertical space, shift space, high limit (H), and low limit (L). See Section III d,7. The last two values H and L are known at this moment. Press Release and then Start and the computer will proceed by plotting this projection again, but now in the desired alphanumeric format.

When it was not a projection but a section the program switches might have to be reset before proceeding with the next section, but not necessarily.

9. Recapitulation of the use of program switches 2 and 3.

i. P.S. 2 off; P.S. 3 off.

Alphanumeric output with 38 characters (A-9).

ii. P.S. 2 off; P.S. 3 on.

Alphanumeric output. Characters /-9 are printed and the characters A-R are transcribed as spaces.

iii. P.S. 2 on; P.S. 3 on.

First numerical output followed by an alphanumeric output (after resetting the switches) of the same projection or section.

iv. P.S. 2 on; P.S. 3 off.

Numerical output.

10. Message

"Type number of groups"

This message requests the typing in of the total number of "groups <k>". The meaning of the term "group <k>" was explained in Section I.

If one erroneously types in this number too small, it will result in error type out; ER 1, which means that the assigned area for the first summation is too small and overflows. The program has to be reloaded in this case. Typing in the number too large does not have immediate repercussions. It can only result in an unnecessary ER 2 type out (momentary overlap of 2nd summation amplitudes and answers; see Section I), because the area assigned by the program to the first summation answers is larger than necessary.

For a projection the number of "groups" is the total number of data.

#### 11. Message

"centrosymm = 1, noncentrosymm = 0"

Essentially all space-groups are dealt with as either  $P_1$  or  $P_{\bar{1}}$ .

In the first summation only the terms A-D are used when the space-group is centrosymmetric (type in 1), while all terms A-H are used when the space-group is noncentrosymmetric (type in 0). (See also Sections I and II.)

More time is won in the program during the first summation by skipping each term, which is zero.

A loss in time might occur in the 2nd summation for certain space groups, but there is no loss in computing time in the third summation by taking this approach.

#### 12. Message

"Load specification tape"

All the specifications of the summations so far described can be put on a tape with an off-line typewriter and loaded instead of being typed, by setting P.S. 4 on.

The first record on this specification tape should be a 6-digit identification (followed by a record mark).

The next record should be a succession of the following specifications:

1st sum min	3 digits
1st sum max	3 "
2nd sum min	3 "
2nd sum max	3 "
3rd sum min	3 "
3rd sum max	3 "
1st sum delta	2 "
2nd sum delta	2 "
3rd sum delta	2 "
1st sum shift	2 "
2nd sum shift	2 "
3rd sum shift	2 "
horiz. spacing	2 "
vert. spacing	2 "
shift spacing	2 "
high limit	5 "
low limit	4 "
number of groups	4 "
: centro/noncentro	1 digit
record mark	1 "

(All but the last two with flags on the left-most digit)

13. Message

"Mcoi"

This is typed out when the calculation is finished.

14. Messages

"Er 1"

"Er 2"

"Er 3"

These messages indicate errors. It will always be necessary to reload the program. Each of them indicate a mistake in planning the calculation, which has to be corrected.

- Er 1: The number of "groups <kl>" is typed in too small (see Section III d, 10).  
Er 2: Momentary overlap of first and second summations answers (see Section III d, 10 and Section I).  
Er 3: Overflow in the 1st summation (see Section III d, 4).

15. Tab stops and margin settings.

i. Numerical type out.

With 16 answers on a row the margins should be 86 positions apart.

There should always be tab stops at the 4th and 42nd position from the left margin.

ii. Alphanumeric type out.

The margin will depend on the shape of the grid which is chosen.

There should be a tab stop at the 42nd and 5th position (the last may be changed) from the left margin.

16. More details of the program can be obtained from the flow sheets and program listing. The author would appreciate notification of program errors. I would like to thank Miss Evelyn Wydro for preparing the program tape and typing this manuscript.

IV. Example

A part of a Fourier projection (001) of the compound 6-azidopurine will be calculated.

The spacegroup was taken as P nam. The actual spacegroup is P na<sub>2</sub>1, but this does not change the appearance of the projection along the c-axis, which we want to calculate.

In the International Tables, Vol. I, the formulas for the space group P nma are given. In the expression for the electron density therefore the b- and the c-axis should be interchanged, giving on a arbitrary scale (leaving out the parts for  $\ell$  is odd).

$$\rho(xyz) = \sum_{h,k}^{\infty} F(hkl) \cos 2\pi hx \cos 2\pi ky \cos 2\pi \ell z \\ \quad h + k \text{ even, } \ell \text{ even} \\ - \sum_{h,k}^{\infty} F(hkl) \sin 2\pi hx \sin 2\pi ky \cos 2\pi \ell z \\ \quad h + k \text{ odd, } \ell \text{ even} \quad (\text{IV},1)$$

This means that for  $h - k$  even,  $F(hkl)$  is equal to the term A and for  $h + k$  odd,  $F(hkl)$  is equal to the term B (see formula I,2:  $\cos \cos \cos \rightarrow A$ ,  $\sin \sin \cos \rightarrow B$ )

In the output we would like as horizontal coordinate x and as vertical coordinate y. This implies a sorting order okh. According to Table II, A, the data should therefore be punched as follows:

k h A B  
00 xx xx xxxxx 00000 00000 xxxxx #, as is shown in the print out of the data tape.

Two examples follow. P.S. 4 should be off in both.

a. We want to calculate the projection from  $y = 0.28$  up till  $y = 0.47$ , with intervals of .01 and from  $z = 0.00$  up till  $z = 0.30$  with intervals of .02.

The third sum shift order is taken as 05 which is not necessary with respect to overflow, but convenient.

We want an alphanumeric output thus P.S. 2 is off. Horizontally we want one extra space between the answers and vertically no extra space in order to obtain the approximate dimensions of the grid ( $a = 11.72 \text{ \AA}^\circ$  and  $b = 17.06 \text{ \AA}^\circ$ ). The shift spacing should be zero because it is an orthorhombic space group and the axes are perpendicular.

From a previous calculation of this projection we know that the answers are roughly in between -200 and +800. We want only the peaks and not the base level thus P.S. 3 is on. If we now should put H equal to 00800 and L equal to 0200, we should only print for answers with a numerical value above +300 (see Section III d, 8), and should suppress the printing of quite a large, and possibly important, part of the peak. This can be evaded however by making L lower than -200, for instance: -550. Doing so all answers with a numerical value above +125 are translated into an alphanumeric character and printed, thus plotting a larger part of the peak.

The number of groups is 0194 and this can be checked in the print out of the data tape as being the number of data of the projection.

The messages and results of this first example are shown in figure IV, A.

b. The second example is a numeric print out (P.S. 2 on) of the same part of the projection. The only difference is that now the interval along the y-axis is taken as .02 instead of .01. The value p (explained in Section III d, 3) would then become a non-integer however. This can be corrected by typing in an even instead of an odd value for y max., for instance 0.46. We want only the numeric print out and P.S. 3 should therefore be off.

The messages and results of the second example are given in figure IV, B.

\* PROGRAM SWITCH  
\*\*+NUMBER OF GROUPS IN SPECIFICATION RECORD IS TOO SMALL.  
\*\*\* SHIFT ORDER IN THE 1ST DIMENSION SHOULD BE INCREASED.

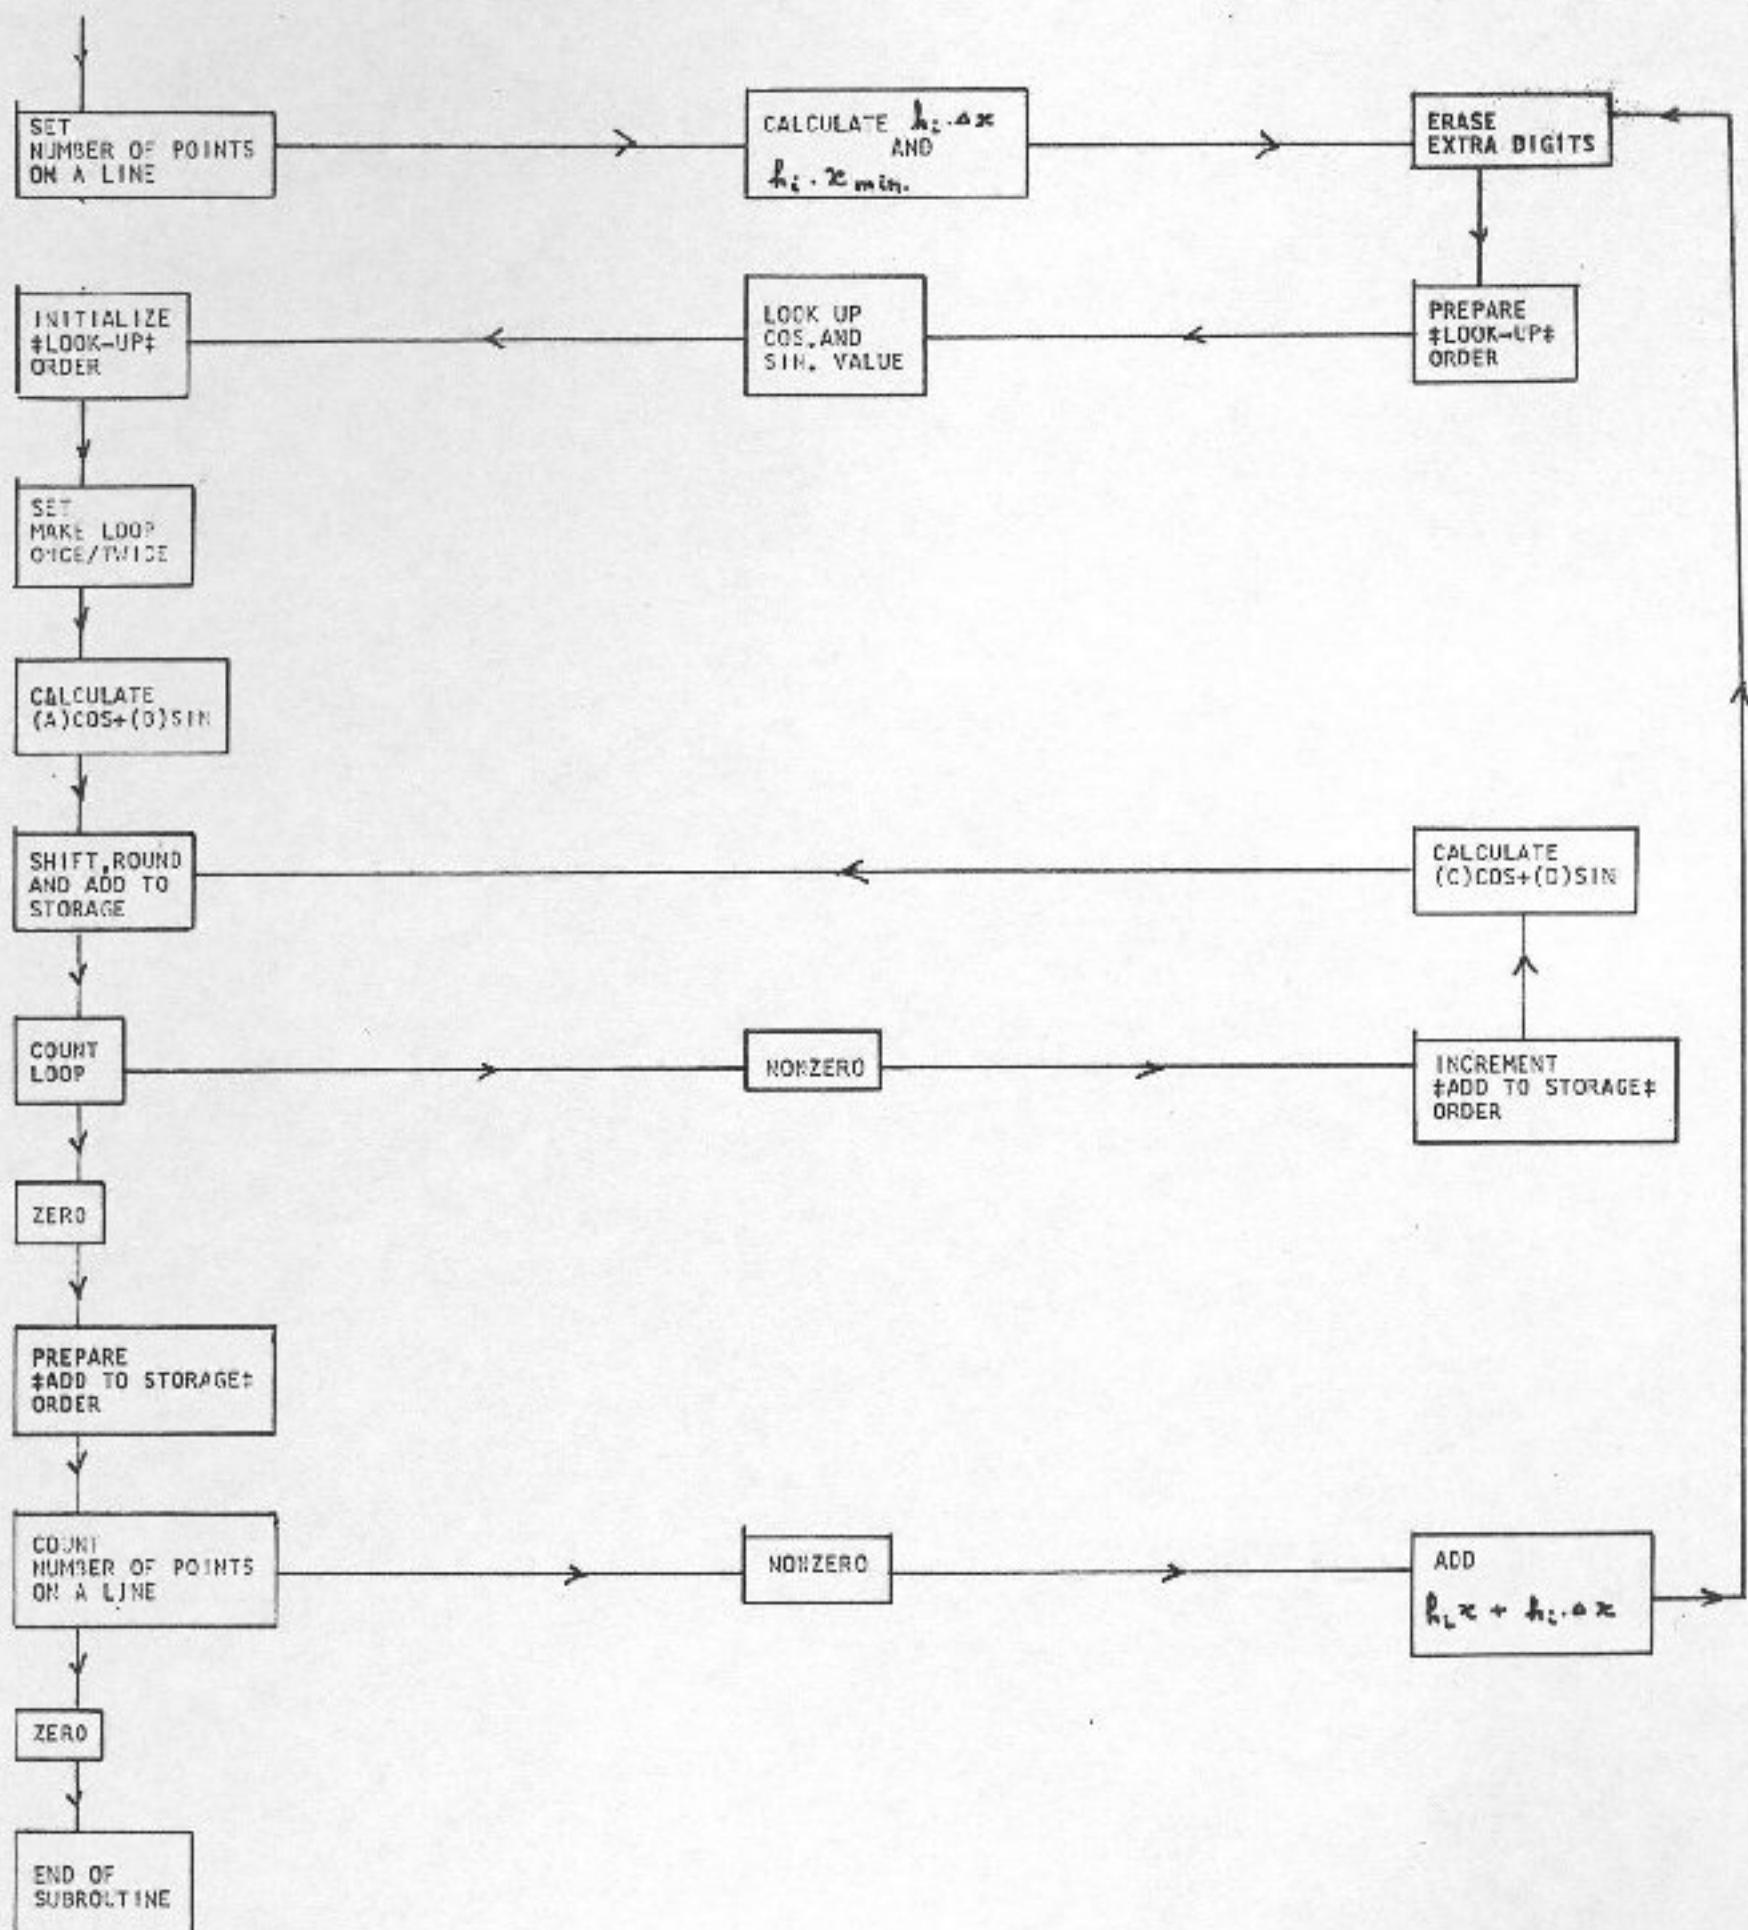

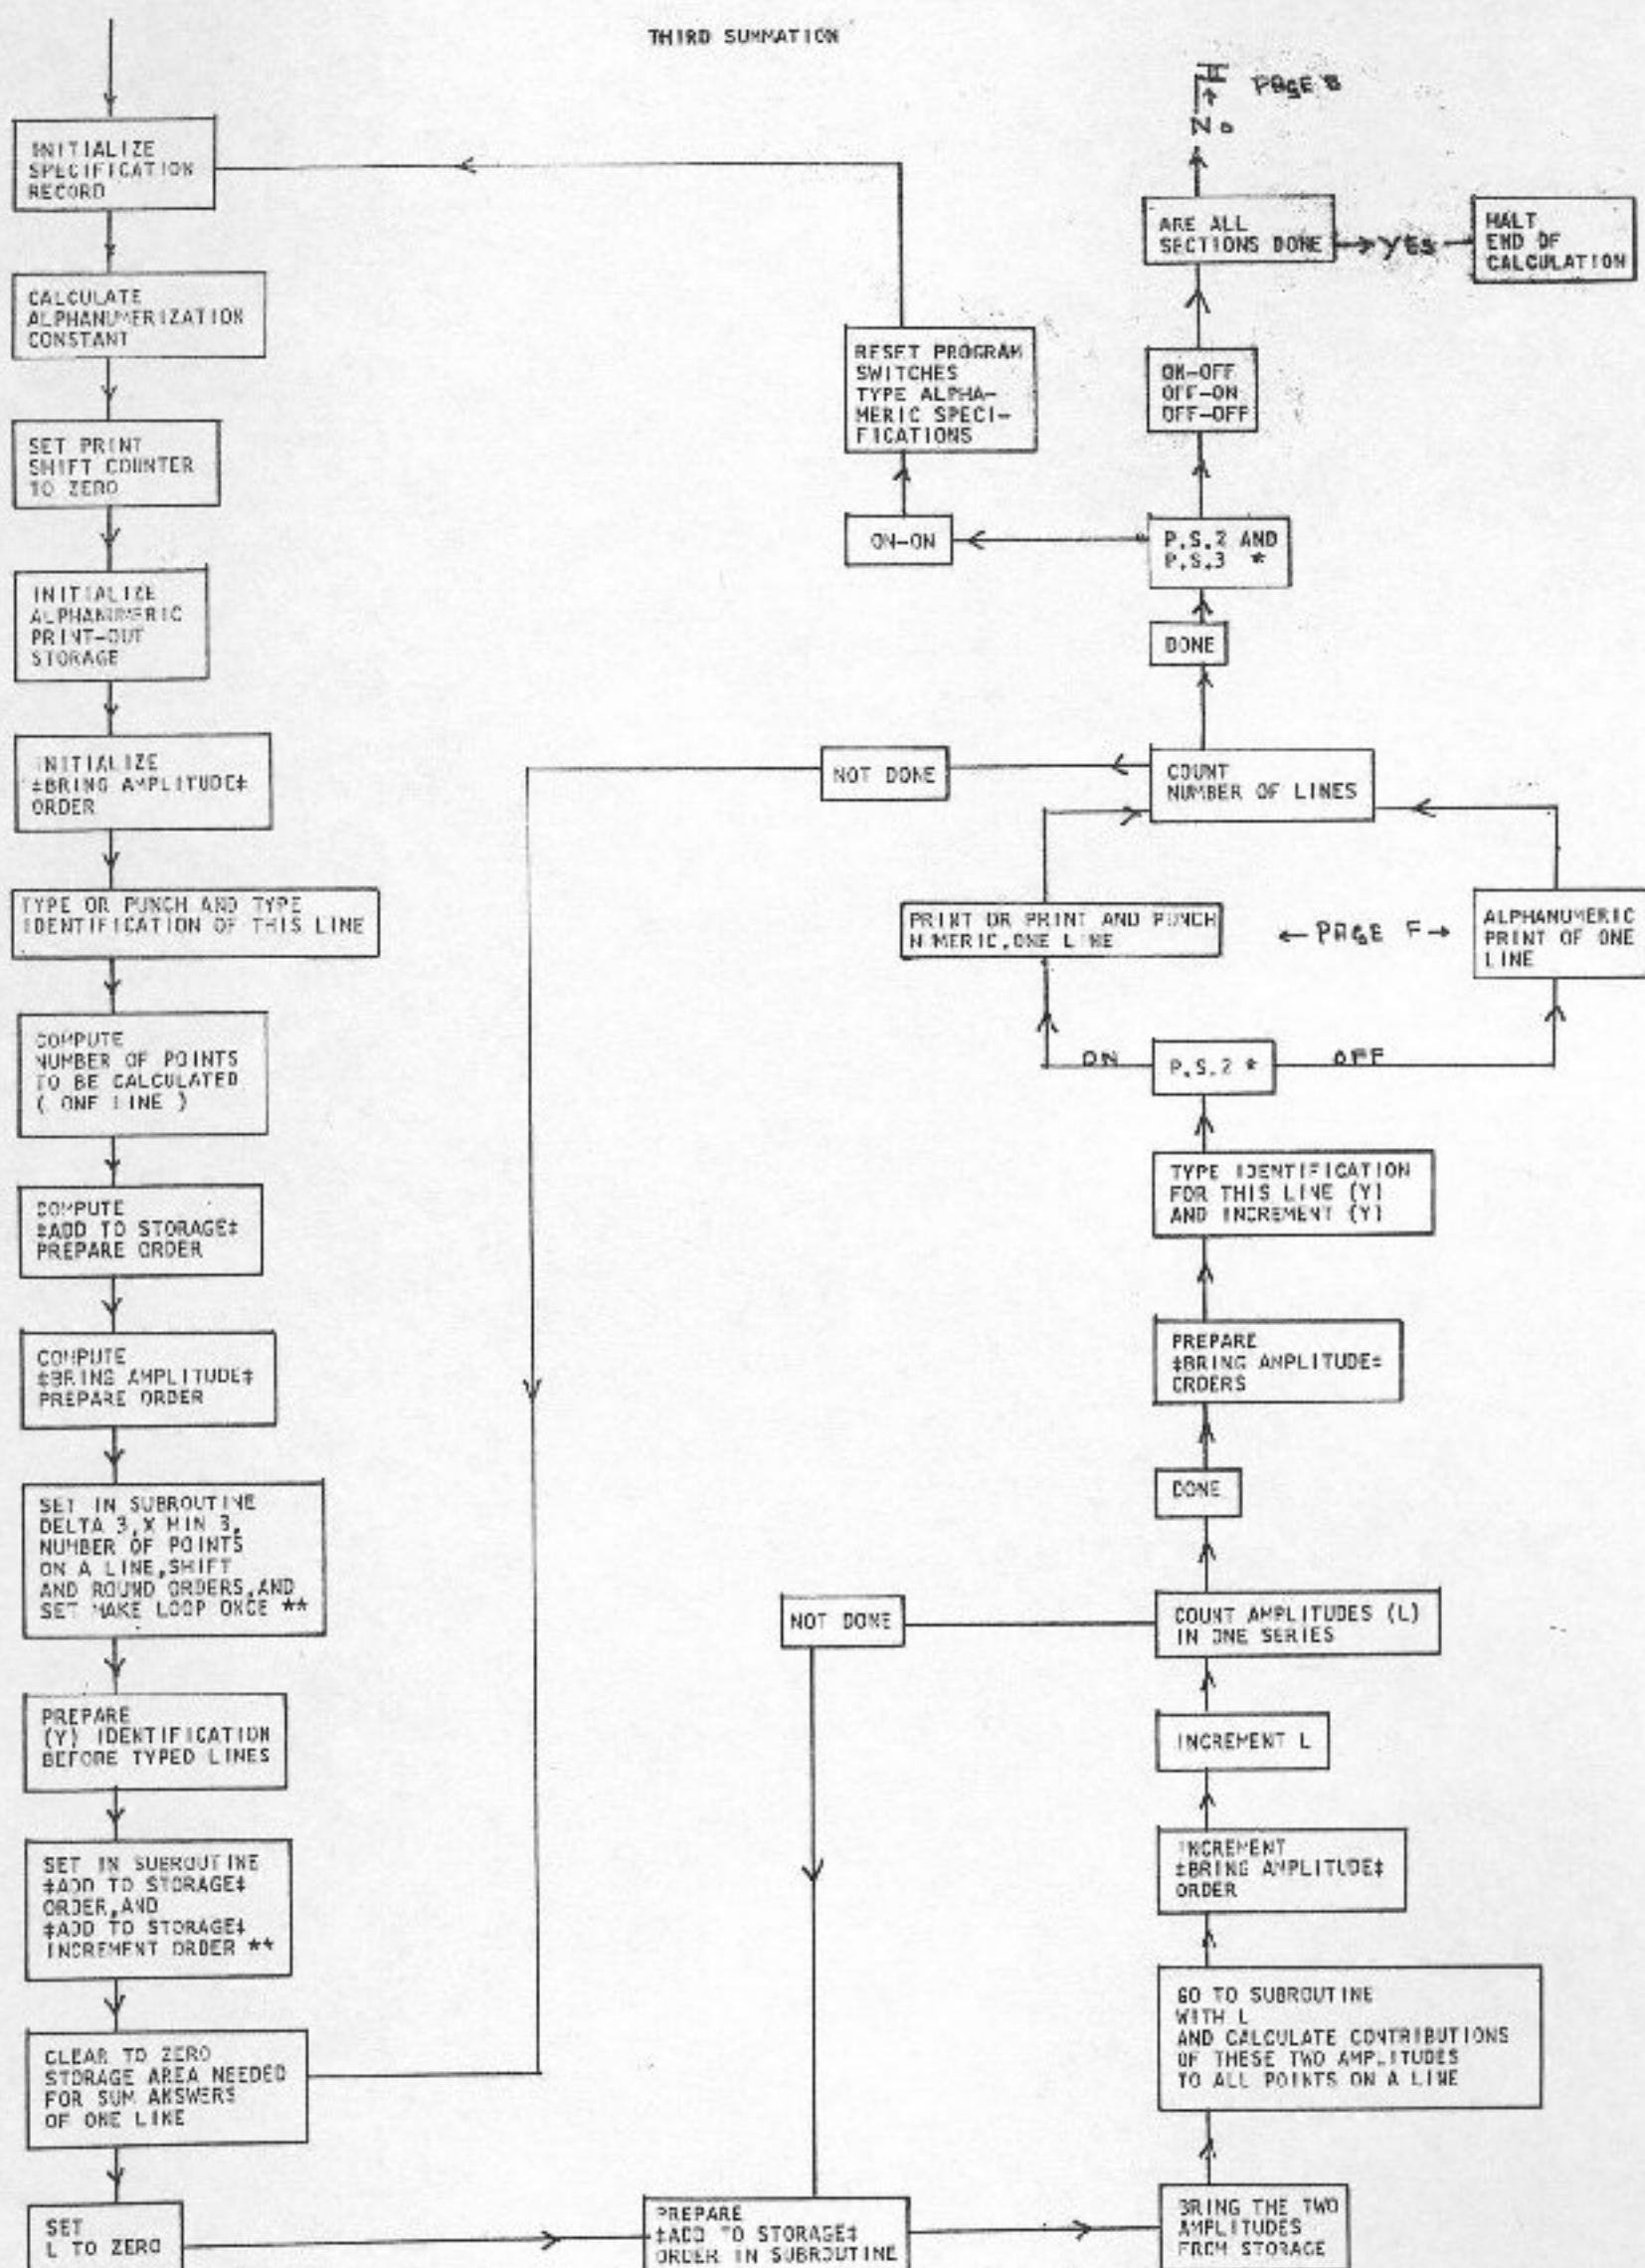

\* SEE SUBROUTINE

\* SEE SUBROUTINE  
\*\* THIS IS A CHECK TO SEE IF THERE IS A MOMENTARY OVERLAP OF FIRST AND SECOND SUMMATION (AMPLITUDES-SUM ANSWERS).  
THE FIRST SUMMATION ANSWERS (HERE AMPLITUDES) ARE USED SERIALLY WHILE THE SECOND SUM ANSWERS ARE STORED SERIALLY.  
THE SECOND SUM ANSWERS ARE STORED FROM POSITION 05000 - LP, WHILE THE FIRST SUM ANSWERS ARE STORED UP TO LOCATION 19479.  
\*\*\*THE POSITIONS OF K AND L AND OF FIRST AMPLITUDE ARE INITIALIZED DURING THE FIRST SUMMATION.
